THE CAUSES AND TREATMENT OF CHRONIC BACKACHE

WITH A CONSIDERATION OF THE DIAGNOSIS OF SACRO-ILIAC "RELAXATION"

ROBERT W. LOVETT, M.D.
BOSTON

That chronic backache, or chronic lameness in the back, is a frequent occurrence is a matter of common information to the medical profession, to the laity and to the manufacturers of patent medicines. The laity, as a rule, attributes such backache to "kidney disease" in men, and to that or to uterine disease in women. The writings of the medical profession on the subject have not led to a clearing up of the matter, and many confusing statements are to be found.

The more common of the various names given to this symptom-group are a sufficient comment on the situation. They are as follows: neurasthenic spine, hysteric or irritable or railroad spine, chronic lumbago, uterine backache, static backache, relaxation of the sacro-iliac joint, sacro-iliac strain, rheumatism of the spine, chronic back-strain, etc.

It seems permissible, therefore, to make an attempt to present what facts are obtainable bearing on the etiology and pathology of the symptom-group, although the results of any classification not based on post-mortem findings must always be unsatisfactory.

In this consideration tuberculosis of the spine, organic nervous disease and the results of spinal fracture are omitted.

SYMPTOMS

The routine symptoms of the affection will best identify it, and may therefore be presented in outline at this point. The most important are an insistent or intermittent dragging, or more or less acute pain most often in the lower part of the spine, sometimes unilateral, sometimes bilateral, generally aggravated by standing or walking, and often shooting down into the buttocks and the backs of the thighs. Lameness in bending may be present. Tenderness is generally to be found over the lower lumbar region, and particularly over the region of the sacro-iliac joints. When the patient lies or sits she prefers to have the small of the back supported by a cushion. The affection may have begun slowly, or sharply with a catch in the back. Coccygodynia is not an unusual sympt[illegible]

It is more common in women than in men, anc [illegible] three types of figu[illegible]

nent buttocks and a sharp lumbosacral forward cur (the overfeminine type of Reynolds[2] and the kangar type of Dickinson and Truslow) and (3) cases slight lateral curvature. As a whole the resistance these patients is less than the average; many of th are neurasthenic, and the affection is notorio chronic. It may vary from a slight backache occur after exertion, to a degree which makes the pat an invalid.

FUNDAMENTAL CONSIDERATIONS

Certain fundamental facts lying at the root of problem under consideration are as follows:

1. We are studying the painful condition of upright, jointed, weight-bearing column, supported unstable equilibrium on the pelvis, to which it attached by the sacro-iliac joints. This column ben more easily to the front and back than to the sid and the upright position is maintained by muscul effort. Since the upright position of the body is mai tained in balance by muscular effort, and since general muscles in their size are proportionate to demand on them, one may obtain information as to balance of the body by comparing the size of th muscles at the front and back of the body. Th gastrocnemius is much larger than the anterior le muscles, whereas in the thigh the anterior muscles ar developed to hold the knees extended in standing, s that anterior and posterior muscles possess about th same diameter. At the level of the pelvis, however the great gluteal muscles have practically no anterior antagonists, and the erector spinae muscles are much heavier than the anterior abdominal muscles. The body, therefore, is to be regarded as balanced against an anterior load, as the posterior muscles are much heavier than are the anterior. That the body of the cadaver falls forward if placed erect with the knees prevented from flexing is well known.

2. The sacro-iliac joints transmit the weight of the spine to the pelvis and thence to the legs. They are ear-shaped articular surfaces of irregular contour, in general vertical in direction, containing some synovial membrane and heavy ligamentous bands. That they permit some motion is well established, but this amount of motion is small. Klein[3] found that 25 kg. of force applied to the symphysis [illegible] the sacrum fixed produced a rotation of th[illegible] the sacrum, which on the average, measur[illegible] excursion of the symphysi[illegible] 3.9 mm.

Horlick's will also serve Horlick's Malted Milk Ice Cream, which has made the "Horlick Booth" so popular at co ventions all over the country.
he McIntosh Portable own.
sine Gen Specialties wi

nan. Measured at the sacro-iliac joint this excur- ı was about one-sixth of this amount; that is, in n the average amount of motion in the sacro-iliac ıt, measured at the posterior part of the joint, was ut 0.6 mm. These joints are protected against ch motion by intra- and extra-articular ligaments the heaviest variety. In front of them lie the nbosacral cord and sacral plexus.

3. The spinal column itself is an intricate structure vertebrae in contact with each other by two interrtebral articular surfaces and by four articular rfaces on the transverse processes, with of course 'o additional articulating surfaces for ribs in each rtebra in the dorsal region. The ligaments conecting the vertebrae are heavy and stronger on the terior than on the anterior aspect. Here then we 've a structure with about one hundred articulations d with intricate and firmly attached ligaments.

VARIETIES

Having investigated these fundamental considera-ıs, we come to the investigation of the causes of ronic backache. We can identify clinically three iologic classes about which there is no reasonable ubt.

1. Disease or displacement of the pelvic organs is iiversally recognized as one cause. Whether this is ue to a direct reflex influence, or because the patient inclined to assume a forward bent position to ease nder pelvic organs[2] and thus incur muscular backtrain, is not certain, although the clinical evidence 'ould seem to favor the latter. It is often the case hat in cases clearly of pelvic origin a successful peration fails to relieve the pain in the back until atment addressed to the static side of the case is bsequently added.

2. Traumatism to the back is frequently followed by chronic backache, and a traumatic class is generally accepted. The spine with its hundred joints and complex ligamentous support is as likely to be sprained as is any other joint, and from the difficulty of fixation of the spine such sprains are as a rule imperfectly treated, and a condition of chronic irritability is likely to arise similar to what we class as chronic sprain in the ankle and knee.

3. Finally, arthritis of the spine is a painful condition universally admitted. It may be the outcome of trauma or it may arise so far as we know spontaneously. It may exist in connection with arthritis elsewhere, or it may exist alone. It may be mild or severe and occurs most often at or after middle life.

But these classes, distinct as they may appear in a theoretical classification, are not always so clearly to be identified in practice, and many cases are seen which must be recognized as a mixture of these classes or as a mixture of one of these varieties with the group *next to be taken up.*

Having defined and set aside cases belonging to these three divisions we have still left unclassified what in p[illegible] practice in the United States constitutes a [illegible] ion of the cases (forty-one out [illegible] be pre-

relaxation of the sacro-iliac joint or joints. It is necessary therefore before proceeding further to examine the evidence for and against these theories, so far as may be done under the conditions.

THEORY OF STATIC ORIGIN

To consider first the theory of static origin: In a paper by Reynolds and Lovett[4] the conclusion was reached that backache of this character was caused by a forward displacement of the center of gravity of the body, causing undue strain of the posterior musculature of the body, and that this muscular strain was expressed as pain in the muscles and ligaments of the back, so that this type of backache was to be regarded as a symptom-complex due to abnormal attitude induced by peculiarities of the skeleton, lack of proper muscular balance or abnormal conditions in the abdomen.

The pain in the buttocks and back of the thighs is to be explained by the fact that the posterior musculature of the body is more or less continuous, and that the posterior irritation may be expressed as pain below as well as above the pelvis. This is, moreover, the reason that in such cases it is generally painful when lying on the back to have the leg flexed with the knee straight, which immediately pulls on irritable and overstrained posterior muscles.

Such a condition of pain and irritability would *a priori* be expected to occur in persons of diminished resistance or peculiar figures from continued strain of the posterior ligaments, fasciae and muscles of the back, and pain and tenderness in the neighborhood of the sacro-iliac joints occur, because here the erector spinae muscles have their origin, and pain at muscular origins and insertions is not unusual under conditions of prolonged muscular strain, as in flat-foot.

SACRO-ILIAC STRAIN

Given the conditions of such struggle against an anterior load, the result of attitudinal strain, it is not unlikely that in some cases the sacro-iliac joints may share in the process and become the seat of an irritation properly to be spoken of as a strain, and the same is very likely true of the integral joints of the spine. But to assume that there is a specific entity to be classed as sacro-iliac strain seems hardly warranted by the evidence, because all the symptoms attributed to it are more reasonably to be explained by a general attitudinal strain in which tenderness over the sacro-iliac joint or joints may be due just as well to muscular and ligamentous irritation as to joint-strain, and secondly, because the treatment to be described — a treatment generally successful — is addressed to the correction of attitudinal strain and not to the relief of a specific sacro-iliac strain.

SACRO-ILIAC RELAXATION

The assumption of a real sacro-iliac relaxation or subluxation lays itself open to a more definite line of proof or disproof, and that such an assumption is seriously made is shown, for example, in an article by Meisenbach[5] analyzing 84 cases of "sacro-iliac relaxation." A quotation from this article will repre-

Chas. Lentz & Sons, Philadelphia. Space 35. An extensive exhibit of many newly devised instruments will be completed for the occasion and the great diversity of apparatus shown will make this display of interest to all branches of the profession. A great many of the instruments to be shown have been perfected through the cooperation of a number of prominent surgeons of Philadelphia.

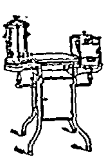
V. Mueller & Co., Chicago. Spaces 29-30. A complete line of surgical instruments, electrically lighted diagnostic instruments, and in fact all modern surgical appliances will be demonstrated. Among other bone-operating engines will be shown the Martel Automatic Engine for cranial operations or for general bone operations. A number of new x-ray accessories, such as screens, protecting devices, measuring instruments, etc., will also be shown.

George P. Pilling & Son Co., Philadelphia. Space 51. The Faught Blood-Pressure Apparatus will be demonstrated by an expert on blood-pressure. A Faught apparatus will be shown that during the past two or three years has been recording more than 1,500 times up to the 450 point. The apparatus is only intended to register to 300 point. This particular demonstrating instrument has been used not only up to 300 point, but again half way around, which is equivalent to 450 mm.

Precision Thermometer and Instrument Co., Philadelphia. Space 13. The many features which make for accuracy in diagnostic work as determined by the use of the new Nicholson Sphygmomanometer will be demonstrated. This mercurial apparatus is easy to read, simple to operate, records both systolic and diastolic blood-pressure, is not affected by climate or temperature and small in size so that it can be carried in the pocket.

Scholl Mfg. Co., Chicago. Space 58. Physicians who are interested in orthopedic work will be interested in the demonstrations to be given at this booth. The orthopedic appliances originated by this firm offer practical and unique methods of fitting corrective supports to the individual foot.

Taylor Instrument Companies. Spaces 24 and 25. At this exhibit a staff of trained medical men will demonstrate the use of the "Tycos" sphygmomanometer in general practice. The demonstrations will cover the taking of systolic, diastolic, and pulse-pressure. New booklets and other literature on the relation of blood-pressure in diagnosis of acute and chronic diseases will be distributed. Besides the "Tycos" sphygmomanometer, this exhibit will include a display of "Tycos" fever thermometers.

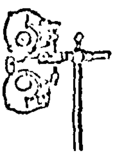


Wilmot Castle Company, Rochester, N. Y. Space 73. Those interested in sterilizing equipment for hospitals will find the Castle Pressure Dressing Sterilizer for bed pans of particular interest. This firm will also show the newest Castle-Rochester Outfits designed for offices and small hospitals; a Catheter Sterilizer; small Water Still; Milk Pasteurizer, etc. Information in regard to the design and construction of the complete line of Castle Hospital Sterilizers will be supplied.

ULTEX
ONEPIECE
LENS
THE PERFECT BIFOCAL

Wall & Ochs, Philadelphia. Space 27. The Ultex "one-piece" Bifocal Lens will be exhibited. This appliance is formed from a solid piece of crown glass and having two wholly distinct spherical curves upon one surface. In this lens there is no zone of cloudiness, no distortion of the object being viewed and no rainbow colors.

The Physicians Supply Co. of Philadelphia. Space 48. A full line of high grade surgical instruments, especially the latest in nose and throat specialties; also electrically lighted diagnostic instruments, sterilizers, bags and medicine cases will be displayed.

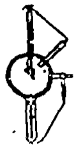


Michael Woolf, New York City. Space 15. This firm, known as "The ℞ House of New York," will exhibit many attractive ophthalmic specialties, including the new model of their Ski-optometer and combined muscle test. Their eye, ear, nose and throat adjustable electric bracket and lamp and other electric specialties have always made their exhibit a most interesting one.

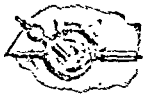
Apparatus—Electric

DeZeng-Standard Co., Camden, N. J. Space 78. Several new instruments will be exhibited. Among them a socket current controller embodying new and highly important features; an improved type of Electric Ophthalmoscope; a greatly improved model Naso-Pharyngoscope having external snap contact and upright image; a line of new instrument tables; a new electric near-point muscle test for use with the DeZeng Phoro-Optometer. Also a full line of electrically lighted diagnostic instruments for eye, ear, nose and throat work. Demonstration daily.

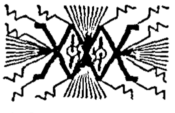
Electro Surgical Instrument Company, Rochester, N. Y. Space 38. Instruments made by this firm are constructed after the designs and suggestions of many physicians based on their practical experience. A line of electrically lighted diagnostic and operative instruments will be exhibited, such as urethroscopes, proctosigmoidoscopes, mastoid transilluminators, cystoscopes, nasopharyngoscopes, etc. Controllers and socket cautery transformers will also be shown.



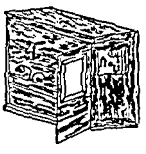
Green & Bauer, Inc., Hartford, Conn. Space 91. The well-known Clover Leaf X-Ray Tubes will comprise the main feature of this exhibit. It will be explained why the quality of these tubes is unsurpassed for all purposes and physicians will be enabled to observe the proper technic of manipulating them as demonstrated by experts in radiography and phototherapy.



Macalaster, Wiggin Co., Boston and Chicago. Space *57. A fine line* of x-ray tubes and accessories will be shown. They have developed a new water-cooled tube which *radiographers* state is doing *splendid* work. The target is of tungsten, and the water chamber is large, allowing long, continued runnings without over-heating. The regular line of tubes and accessories also will be shown.



The Wm. Meyer Co., Chicago. Space 47. A demonstration of their well-known line of interrupterless X-Ray equipments with the latest improvements in same, in the *way* of radiography and fluoroscopy without any guess work, also a moderate-priced klinoscope, which will do both vertical as well as horizontal fluoroscopic work. All the other various X-Ray appliances made by this company will be demonstrated.

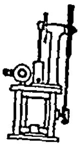


McIntosh Battery & Optical Co., Chicago. Space 81. There will be demonstrated a new X-Ray Transformer, *combining speed, efficiency* and protection. Visiting radiologists will be presented with a valuable x-ray appliance especially prepared for this meeting. The McIntosh Universalmode, Polysine Gen [illegible], Portable Coils and other specialties wi [illegible] own.

E. B. Meyrowitz, Inc., *New York*. Space 43. Will exhibit a full line of ophthalmological apparatus and special instruments. Among *these might be mentioned* the Marple Electric Ophthalmoscope, Klaar Headlight, Zeiss Magnifying Loupe, a most convenient form of Pocket Battery, a "Shockless" Rheostat, a new form of Mouth Gag, Nernst Operating Lamp and a full line of eye, ear, nose and throat instruments.

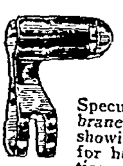
E. Machlett & Son, New York City. Space 103. X-Ray tubes for *deep therapeutic* and *radiographic work will* be demonstrated. Physicians will be given an opportunity to see the tube in operation and the technic of applying it therapeutically will be explained.

Scheidel-Western X-Ray Coil Company, Chicago. Spaces 107-108. Whether you are an x-ray operator *or not, this exhibit will* prove particularly interesting. Demonstrations will be given daily of the latest apparatus for roentgenoscopic examinations. There will also be shown a new *interrupterless* transformer which is said to be the first machine of this type where both the voltage and amperage will be under absolute control at all times.



***Victor* Electric Co.**, Chicago. Spaces 63 and 64. New apparatus and accessories brought out since the Minneapolis meeting will constitute the exhibit of this well-known concern, and there will be plenty to interest every physician or surgeon, regardless of his specialty, for this *firm reports* that it has broken more of its records for turning out new apparatus, during the past year, *than* during any similar period in its history.

Wappler Electric Manufacturing Co., Inc., New York City. Spaces 22 & 39. A large exhibit of electro-medical and therapeutic apparatus and electro-surgical and diagnostic *instruments*. There will be demonstrated the *interrupterless* King model X-Ray machines and interrupterless treatment type X-Ray machines which are fitted with their new single-impulse timer, and also fitted with a new serial timer. The exhibit will also include the Excell high frequency machine and a complete line of cystoscopes, urethroscopes, *headlights*, diagnostic instruments, controllers, pantostats, galvanic and faradic wall plates, etc.



Weder Manufacturing Co., Philadelphia. Space 59. A demonstration of the "De Lyte Surgeon," ever-ready case, consisting of electric light, directly transmitted, (1) through Ear Speculum, magnifying tympanic membrane, (2) through Nasal Speculum, showing turbinates, allowing packing for *hemorrhage under direct* illumination, (3) by using attachable Tongue Depressor, illuminating the throat, (4) for transillumination of sinuses, (5) with head-band attachment, for emergency operation.

Foods and Milk Preparations

Borden's Condensed Milk Co., New York City. Spaces 96-97. At these *booths* not alone will the firm exhibit their Malted Milk in powder form, but they will also serve Borden's Malted Milk Ice *Cream*. To those who have tasted this ice cream in the past, this will be a welcome *announcement*. *To* those who have not this is an urgent invitation to try it.

Horlick's Malted Milk Co., Racine, Wis. Space 5. As in past years this firm will display the Original-Genuine Malted Milk, together with Horlick's Food and Horlick's Diastoid. They will also serve the delicious Horlick's Malted Milk Ice Cream, which has made the "Horlick Booth" so popular at conventions all over the country.

HORLICK'S
TRADE
M.M.
MARK
MALTED MILK

The
Mellin's Food
Method of
Milk
Modification

Mellin's Food Company, Boston. Space 55. Physicians are cordially invited to make every inquiry regarding Mellin's Food and its use. Demonstrations will be made to show why there is a distinct advantage to the physician, to the mother and to the baby in the employment of the simple measures suggested in the plan upon which the Mellin's Food Method of Milk Modification is based.

Mead Johnson & Company, Jersey City, N. J. Space 49. An exhibit of their Dextri-Maltose (pure maltose and dextrin in about equal parts) will be made. It is a practical duplicate of the malt-sugar and dextrin preparations made in Germany, where they are largely used by pediatrists, especially those who employ the Finkelstein method of infant feeding.

ESKAYS
Albumenized
FOOD

Smith, Kline & French Co., Philadelphia. Space 9. Will show how Eskay's Food modifies cow's milk. The cereals preventing the formation of hard cheesy curds, while the other ingredients in its composition make up the deficiencies of cow's milk so that it will similate mother's milk.

Welch Grape Juice Company, Westfield, N. Y. Spaces 45 and 46. This firm will have a large and handsome booth in the form of a grape arbor, completely covered with artificial grapes and vines, from which will glow hundreds of tiny electric lights. Here Welch's The National Drink will be dispensed to the Delegates and their friends. In addition to its food value, Welch Grape Juice is being used by physicians as an excellent menstruum in which to administer oily and other disagreeable medicines.

Pharmaceuticals and Biologic Products

Antiseptic Supply Co., Inc., New York City. Space 85. An interesting exhibit of Causticks, Stypsticks, etc., the new form of applying silver nitrate, copper sulphate, alum, etc. Their use avoids the necessity of applying the same applicator in the consecutive treatment of different patients. Samples and descriptive literature will be distributed to all physicians who visit this booth.

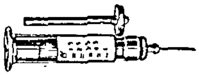
Arlington Chemical Co., Yonkers, N. Y. Space 54. Liquid Peptonoids and Dry Peptonoids Soluble will be exhibited together with Hemaboloids made by the associate of this firm, the Palisade Mfg. Co. A new reagent, Arlco-Urease (a urea- splitting ferment) will also be made a part of the exhibit of the former company. This firm will also conduct an accommodation bureau giving visiting physicians free service for writing letters. Competent stenographers will be in constant attendance.

Armour and Company, Chicago. Space 74. Therapeutic products made from glands and membranes supplied from the abattoirs, such as Corpus Luteum, Standardized Thyroids, Parathyroids, Suprarenals, Thymus, Spleen and Pituitary substances in powder and tablets. Also Pituitary Liquid, a solution of the active principle of the posterior lobe of the pituitary body; Red Bone Marrow, Lecithol, an emulsion of lecithin; Pepsin and Pancreatin in various forms for the profession.

Schering & Glatz, New York City. Space 105. An exhibit of the more recently introduced products of their extensive list of well-known synthetic chemical therapeutic agents. The firm will be glad to give information concerning all of these, as well as their organo-therapeutic and other preparations.

Reinschild Chemical Co., New York City. Space 79. The special ferruginous preparations —formulated by Dieterich—will be exhibited. Also agar-agar combinations prepared for administration according to the formulas of Dr. Max Einhorn.

Fairchild Bros. & Foster, New York City. Space 2. There will be exhibited Essence of Pepsin-Fairchild, the gastric gland extract; Holadin, the entire pancreas gland extract (powder) in enteric capsules; Holadin and Bile Salts; Panopepton, the food for the sick; Enemose, for colonic alimentation; the Fairchild Culture of the Bacillus Bulgaricus in sealed glass vials and in desiccated form in the Lactic Bacillary Tablets, and other Fairchild products.



H. K. Mulford Company, Philadelphia. Space 42. A scientific exhibit of bacterins, serums, sero-bacterins and vaccines. Showing methods of production with working bulletins compiled from the latest information on the special subjects treated. This is not only designed to be an interesting but an instructive scientific exhibit to aid every practitioner.

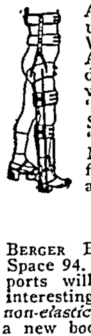
Schieffelin & Co., New York City. Space 6. An exhibit of the biologic products, including diphtheria antitoxin, tetanus antitoxin, antistreptococcic serum, vaccine virus and bacterial vaccines. The method employed in the production of these products will be shown in more or less detail, and will be explained by those in charge of the exhibit. The various containers of the products will also be exhibited.

E. R. Squibb & Sons, New York. Space 72. Will give demonstrations of the disintegrability of their tablets and also exhibit a representative collection of their high quality chemicals and pharmaceuticals, together with some of the impurities removed from the regular U. S. P. grade of products in the process of repurification necessary to bring the articles up to the Squibb standard.

Henry K. Wampole & Co., Inc., Philadelphia. Space 20. Pharmaceutical products will be displayed by this firm, including those prominently identified with U. S. P. and N. F. standards. Pulverous pills, fluidextracts, elixirs, syrups, solutions, tinctures, ointments, soft elastic and hard gelatin capsules, effervescent salts, lozenges, compressed and hypodermic tablets will be aptly displayed in illustration of the advanced achievements to-day of the manufacturing pharmaceutist.

The Zemmer Company, Pittsburgh. Space 23. An exhibit of their line of pharmaceutical products, comprising tablets, lozenges, dry-filled capsules, ointments, eye ointments and hypodermic tablets. This display will be of practical interest.

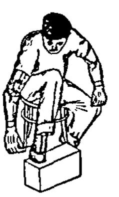
Artificial Limbs, Orthopedic and Supportive Appliances



Ambulatory Pneumatic Splint Manufacturing Co., Chicago. Space 10. Will demonstrate the advantages of Ambulatory Pneumatic Splint for reduction, bed and walking treatment of various fractures of lower limbs, also "Ambumatic" Washable Abdominal Supporters. Also a demonstration of 'Ambumatic" Flaxall Pure Linen Mesh Underwear, and of latest artificial limb, non-visible extension shoes and non-visible orthopedic appliances.

Berger Brothers Co., New Haven, Conn. Space 94. Spencer Abdominal and Spinal Supports will be exhibited. In addition to an interesting showing of supporting corsets and non-elastic belts, a limited number of copies of a new booklet on abdominal supports will be distributed gratis. The booklet analyzes, by means of pictures, the relative merits of various types of abdominal support.

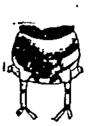
Van Orden Corset Co., Newark, N. J. Space 36. An interesting exhibit in which the La Grecque Surgical Corset will be demonstrated and [illegible] actual results on a specific case, under the [illegible] of a physician of standing, is to be sh[illegible] radiographs.



Carnes Artificial Limb Company, Kansas City, Mo. Space 76. Will exhibit an artificial arm and hand made of steel and fiber of such ingenious mechanical construction as to enable the wearer to automatically bend the elbow, bend and turn the wrist and open and close the fingers. The demonstration will be by men wearing the arm and will consist of such feats as writing, lighting a pipe or cigar, picking up suitcases, satchels, etc.

Spirella
PHYSICIANS APPLIANCES

Spirella Company, Inc., Meadville, Pa. Space 65. Will exhibit their line of physicians' appliances, asking particular attention to their binder over which *measurements are taken*; a new shoulder-brace and poise-correcting belt and corsets for the correction of splanchnoptosis and spinal curvature. The value of their exclusive stay in maintaining support without atrophy will be demonstrated.



Dr. Katherine L. Storm, Philadelphia. Space 66. It has been observed that many physicians use this belt for one or two conditions, as for operations or ptosis, and fail to realize its many-sided usefulness. Fitters employed by the firm will be at this exhibit to explain the efficiency of the appliance as a support in hernias, pregnancy, obesity, sacro-iliac relaxations and other unusual requirements.

Minerai Waters

Apollinaris Agency Company. Space 11. Apollinaris water, which is mildly alkaline and naturally effervescent, will be exhibited. It is bottled only at the Apollinaris spring, Neuenahr, Germany, and only with its own natural gas, as stated on the label. The same company will also exhibit "Apenta," the Hungarian natural aperient water, which is noted for its well proportioned content of magnesium sulphate and sodium sulphate.

Morris & Schrader, New York City. Space 61. An exhibit of Contrexéville water, which will be dispensed *ad libitum*. A full description of the various varieties will accompany the exhibit.

Miscellaneous

Deimel Linen-Mesh System Co., New York City. Space 34. This Underwear was invented by Dr. Henry L. Deimel, a California physician, some twenty years ago. The Seventeenth International Congress of Medicine held in London last August awarded this hygienic underwear a Gold Medal. There will be on exhibit different weights of cloth and the latest style garments.

Indiana Springs Co., Mudlavia, Kramer, Ind. Space 95. For the benefit of physicians who have not had an opportunity to visit Mudlavia, this company will maintain an exhibit showing in pictorial detail their special therapeutic agent, the Mudlavia Bath. Beginning with a view of the mud deposit in the natural state, the various steps in the process to completion of the bath will be shown; likewise the buildings and grounds with their special equipment.

The Pompeian Co., Washington, D. C. Space 88. Patients often refuse to take olive oil because the brand they purchase has a disagreeable taste. At this exhibit physicians will be given an opportunity to examine and taste Pompeian Olive Oil which is an absolutely pure product, pressed from the right kind of fruit, picked at the right time and clarified in the right manner—this care in preparation retains in the oil its agreeable fruity flavor, making Pompeian Olive Oil unsurpassed for medicinal uses.

Radium Chemical Company, Pittsburgh, Pa. Space 62. The exhibit will consist of a display of Radium salts of high purity. These Radium salts are prepared from carnotite ore mined in Colorado. The production of Radium in America in 1914 will amount to twice the old world's production. Demonstrations of the Radium rays will be given daily.

Weissfeld Bros., New York City. Space 85. Hospital wearing apparel, physicians' coats, surgeons' gowns, duck suits, smoking jackets, bath robes, dressing gowns, washable uniforms of every description, etc., will be displayed.

> joint. . . . The symptoms produced by any irregularity of the sacro-iliac joints depend on the pressure of the nerves involved and their distribution.

It is self-evident that a displacement of this joint severe enough to press on the nerve-trunks lying loosely in *front of* it must be evident to roentgenoscopy, yet — I quote again from Meisenbach — "Heretofore to my knowledge no x-ray has been published showing a dislocated or strained sacro-iliac synchrondrosis,"[6] and one has only to compare the roentgenogram of the "open" sacro-iliac (Fig. 4) of the article with the normal one shown on the opposite page (Fig. 3) to see that no evidence has in that instance been offered. In a case of Meisenbach's (Case 40) "movable sacrum" was diagnosticated by him, the symptoms being occipital headache and pain in the shoulder, the neck symptoms being attributed to "referred muscular spasms radiating from the sacrum."

In an examination of the roentgenograms taken of the eighty-three cases in my series (to be reported later) in no one was there the slightest evidence of any disturbance of relation in the joint. Post-mortem and dissecting-room evidence that this condition exists, except in connection with pregnancy and very severe or crushing trauma is so far as I know wanting.[7]

In Case 84 of Meisenbach's series a pathologic examination was made, as the patient died later of tuberculosis. The symptoms had been pain in the dorsal spine and legs following childbirth. At necropsy "some motion, but not marked, was noted." The joints were then sawed through, and by moving the ilia on each other the joints were observed to move "slightly." These findings are practically identical with those obtained in ordinary dissecting-room specimens.

The symptoms ordinarily described as characteristic of sacro-iliac relaxation are so far as I know identical with those detailed earlier in this paper, except that "slipping" of the joint is said to be felt when the patient stands, for example, on one leg and flexes the other and the surgeon holds one hand on the joint and the other over the pubis, or by manipulating the crests of the ilia with one hand on each, or by forced hyperextension of the thigh with the hand over the joint.

In my series of eighty-three cases, all examined carefully in this regard, I have failed to find any suggestion of such slipping or displacement or abnormal motion. It may be that my fingers are not sufficiently trained, but I have heard many of my colleagues confess to a similar disability. Again, in the one case seen by me in the last three years in which I believe that there did exist some slight degree of sacro-iliac displacement (Case 12), the symptoms were of a wholly different character from those described above, and were practically those of tuberculosis of the sacro-iliac joint, a peculiar sidling gait, great pain in walking and an inability to lift either leg properly in walking, with a feeling of instability.

The treatment afforded to cases of "sacro-iliac relaxation" not occurring in pregnancy, and the relief afforded by such treatment, as reported, is of itself the best evidence as to the incorrectness of the diagnosis. We have supposedly a relaxed or subluxated great joint, which bears at every step the whole weight of the body. The plane of this joint and the line of thrust on it are practically the same, that is, every step tends to thrust one joint surface along the face of the other. No joint in the body once relaxed could be so unfavorably situated for recovery while the patient is going about. Yet I quote from another author[8] to show the *treatment generally in vogue and the* mechanics on which it is based:

> A wide belt made of webbing 9 inches wide, extending from the trochanters up to the crests of the ilia, and encircling the pelvis and buckling in front, gives great relief by *immobilizing* the joint.

Again:

> *In mild cases with a movable sacrum, high-heeled shoes* may be all that is necessary (Meisenbach).
>
> In the acute cases an adhesive plaster strapping is applied to the back *to hold the joints together* until a properly fitting belt can be made.[9]
>
> Locally the entire principle of treatment concerns ways and means of *holding these joints together*. In the most severe it may be necessary to use a plaster spica or corset. Various other forms of *retention* apparatus are in use, and in some instances simply wearing a pair of closely fitting elastic silk trunks is sufficient. If it is desired simply to provide *immobilization* for a few days . . . one may strap the pelvic girdle firmly with adhesive plaster.[10]

Plaster jackets and braces of one kind and another to secure lumbar lordosis or pressure on the sacrum are also advocated.

The upshot of all this is that we are asked to believe that a pair of elastic silk trunks, strips of adhesive plaster on the skin, a webbing belt or even a plaster-of-Paris jacket will jam together sufficiently firmly to prevent their slipping by each other, these "relaxed" sacro-iliac joints. These joints, which must bear at each step a downward sliding thrust of from 75 to 125 pounds, are deeply embedded, so far as lateral pressure goes, in great masses of fat and muscle, and we are asked to believe that straps of adhesive plaster on the movable skin will "immobilize" them, that is, prevent them from slipping on each other. Here one must apply the simplest rudiments of physics and an elementary knowledge of anatomy and decide according to his individual habit of mind whether or not "slipping" of the sacro-iliac joint is likely to be prevented by these measures.

Contrasting the two theories then, we must recognize that the static cannot be proved or disproved by the Roentgen-ray or pathologic evidence; that sacro-iliac relaxation can be proved in this way, but that such proof is as yet lacking; that the symptoms described fit the static theory, and that the treatment advocated could easily afford relief in certain static cases by affording an annular ligament to the glutei muscles which hold the trunk erect on the legs, for the blacksmith straps up the muscles of his forearm before starting on heavy work; but it is not possible that the apparatus advocated can have the slightest effect in immobilizing a "slipping" sacro-iliac joint. That sacro-iliac strain may exist in connection with general attitudinal strain seems probable, but that sacro-iliac relaxation is a common cause of chronic backache is apparently still to be demonstrated.

The diagnosis of sacro-iliac "trouble" or "dislocation," "relaxation" or "displacement" is at present a very popular one, and eminently satisfactory to the patient, because it seems serious and unusual, and equally satisfactory to many general practitioners because it seems explanatory. Its adoption demands no etiologic study and only a routine treatment. The diagnosis of "static backache," on the other hand, means that the careful surgeon must look into the cause of it and try to remove this before proceeding to treatment. It is significant that the sacro-iliac diagnosis is but little heard of or discussed in Europe, and that foreign literature on the subject is practically lacking.

[9] Morrill: Cleveland Med. Jour., October, 1910.

[10] Swett: Yale Med. Jour., October, 1908.

The etiology and classification of cases having thus been defined, it becomes important to consider how these theoretical considerations work out in practice, and especially in the treatment of the different groups.

I. BACKACHE OF PELVIC ORIGIN

Pelvic backache, so far as the back itself is concerned, possesses no definite characteristics to distinguish it from backache of static origin, and mixed forms are frequent. In general, pelvic backache is sacral, but may be dorsal, and is generally associated with a history of symptoms pointing to pelvic disturbance. This similarity of back symptoms in static and pelvic cases tends to support the theory that pelvic backaches are most often caused by the forward bent position mentioned above.[11]

II. BACKACHE FOLLOWING TRAUMATISM

In the history of many cases of chronic backache a traumatism in former years of mild or severe nature is to be found. Many of these cases without this history would have to be classed as probably due to defective balance, but the history of a trauma or overstrain in the past makes it doubtful if they belong to that class. Cases of postoperative backache apparently belong in this class.

A very puzzling class of cases lies between the divisions of those associated with trauma and those clearly arthritic. In the acute stage even if they have a traumatic history they are not always to be distinguished from each other, but the recovery of motion under treatment in a few months, of cases apparently arthritic, leads to the belief that they could not have been due to arthritis of any degree, and it seems better to regard them as analogous to the stiff and painful feet resulting from trauma which are spoken of as "chronic sprains," and which also in their acute stage cannot be clearly differentiated from arthritis at the outset.

III. FORMS DUE TO ARTHRITIS

The recognized symptoms of arthritis of the spine are stiffness and lateral deviation of the spine, pain in the back and legs often classed as "sciatica," a loss of the lumbar curve, and in the severer cases localized disturbances of sensation in definite areas in the legs, and sometimes even some loss of motion in some muscles. The leg pains are to be attributed to nerve-root pressure, and the anatomic distribution of the pain and sensitiveness often shows nerve-root pressure rather than an involvement of the whole sciatic nerve. Pain is noticeable on movement, and a "catch" in making some slight movement frequently occurs at the onset, and often in the course of the affection. A history of recurrent "lumbago" is frequent.

Roentgenoscopy reveals in some cases the presence of osteophytes in the vertebrae, and "lipping" or overgrowth of the vertebral edges; but in other cases presenting exactly the same symptoms no such changes are to be found, yet their long-continued course and recovery with stiffness of part of the spine suggests that the latter are also arthritic.

IV. CASES DUE TO DEFECTIVE BALANCE

These may be classed as (1) those due to defective lateral balance, and as (2) those due to defective anteroposterior balance.

Lateral Defects in Balance.—If one leg is longer than the other, the pelvis must become oblique and the spine curved to one side in standing, and the muscles of one side (generally on the convex side of the curve) are under more strain than those of the other side. This is the simplest form of backache due to defective balance. The pain and discomfort will be most noticeable in standing and walking, and will in many cases be marked over the sacro-iliac region, oftenest on one side. In susceptible persons only a slight degree of lateral curve may be required to produce such backache.

Case 7.—A clergyman, aged 40, consulted me in 1910. He had always been conscious of his back, even as a boy, having had pain in the lower part of the back and at the end of the spine. For the last two or three years the backache has been decidedly worse, and he now has great discomfort in the lumbar spine in standing and walking; there is no pain in the feet, legs or thighs. After preaching he becomes exhausted, and his nervous endurance is poor. Examination shows a marked lateral curve of the spine to the left, due to 1 inch shortening of the left leg from an unknown cause. This was corrected by a high sole on the left boot, and relief from the backache came in about three weeks, accompanied by very marked improvement in general health and endurance. Two months later he was practically well, and has remained so.

Defective Anteroposterior Balance.—The simplest type of this variety of backache is shown when the abdomen is so large as to cause a serious anterior load.

Case 8.—A man of 55, in active business, vigorous and athletic, was referred to me in July, 1912, by Dr. S. J. Mixter of Boston, for a persistent lumbar backache of many years' duration, which came on in standing and walking but not in horseback riding. It was so severe that the patient had recently avoided all possible standing and walking. The back was flexible, but the back muscles were spasmodic and hard to the touch. The abdomen was very large and lax. A close-fitting corset was applied to support the lower abdomen, and immediately partial relief was felt. In two weeks the pain had disappeared, and a year later the abdomen was smaller and much less lax, and there was no pain whatever unless the corset became loose. At this time the patient was given exercises for the abdominal muscles.

That defective anteroposterior balance may be manifested by pain in other posterior muscles than those of the back is shown in the following case:

Case 9.—Woman, aged 25, single, referred in June, 1909, by Dr. Ansel G. Cook of Hartford, who had at one time treated her, complained of great discomfort, especially at the back of the knees, aggravated by standing and somewhat by walking. The pain was attributed by the patient to varicose veins, and she had many cramps, especially in the right leg. The patient stood with an increased curve in the lumbar region, and there was a loss of dorsal flexion in both feet. The gastrocnemii were stretched, higher heels were put on the shoes, and a therapeutic corset was applied.

---

[11] Cases illustrating backache of pelvic, traumatic and arthritic origin are omitted in this place for the sake of brevity. Complete reports of these cases will be given in the author's reprints.

The patient was dissatisfied with the opinion that varicose veins were not the cause of her trouble, and disappeared. In December, 1910, she returned to report that she had had complete relief of all her symptoms shortly after her first visits. When the therapeutic corset wore out and failed to give her support she had much trouble again in the legs, but on getting a satisfactory corset again the pains in the back of the legs disappeared.

In other instances, anteroposterior balance is disturbed by flat-foot and similar conditions, which, by affording an abnormal base of support, induce back-strain.

Case 10.—A healthy and vigorous domestic servant, aged 30, consulted me in 1907 for a flexible flat-foot, which gave more trouble in the hips and back than in the feet. Flat-foot plates relieved the pain in the hips and legs, but the backache was so severe that a corset and shoulder-straps were applied, which finally relieved the pain in the back. The patient remained comfortable till 1912, when some friends induced her to discard the plates and wear a boot with a low heel and flexible shank. In two weeks the backache became intolerable, and she was unable to work for a day or two. She reapplied the plates, and her symptoms disappeared.

Backache due to relaxed and slumped attitude is perhaps the commonest type of static backache.

Case 11.—July, 1908, a girl, aged 15, reported that for some years she had had pain in the hip and sacral backache, diagnosticated as sacro-iliac joint affection. The general attitude was bad, the spine being decidedly rounded in the dorsal region. The spine was tender to the touch, and the girl's endurance was poor, the patient having been out of school for a year and a half. She returned for treatment in September, 1908. She was given a therapeutic corset and started on exercises, which she did daily. Setting-up exercises of a very gentle character were at first given in the recumbent position, and were made more forcible and given in the erect position. After two weeks' treatment the patient was allowed to go home, with directions to lie down half an hour in the afternoon, to take half an hour of active exercise outdoors three times a week, to pursue the exercises, and to go to bed at 8 o'clock each night. The pain in the back gradually disappeared, and after a few months there was no further trace of it.

Finally, there are cases apparently due to defective balance in which the pelvic organs are normal, there is no history of trauma and no reason to suspect arthritis, and yet no gross malposition in the standing position is to be detected. It must be remembered with regard to these cases that we have as yet no reliable normal for the upright position to guide us, that individual variations are many, and that in a given person it cannot be said that he or she stands in such a way that back-strain is not to be considered.

FREQUENCY OF DIFFERENT FORMS

Having thus presented the types of backache with which I am familiar, I proceed to the analysis of 83 cases seen by me in 1912 in private practice either at my office or in consultation, in order to see what they show as to the relative frequency of the different forms. Of these cases 29 were males, and 54 females. In age, the patients ranged from 10 years to over 70, with a fairly even distribution by age periods, but rather more frequent between 15 and 20 and between 35 and 50 than at other ages. As to duration, only 6 were of less than six months, 14 were from six months to a year, four were from ten to fifteen years, and 9 were said to have lasted "many years."

As to the classification into the groups described I found as follows:

Lateral defect in balance, 10, (three of these occurring in bony lateral curvature).

Anteroposterior balance, 31. (Five were due to large abdomens, and in fifteen cases there was some static error in the feet which seemed to have an influence on the defective balance.)

Pelvic, 6.

Traumatic, 20. (Five of these were associated with obviously bad standing positions, but in the others the trauma seemed the only cause.)

Arthritis, 15, (in which must be included two cases of "recurrent lumbago" probably arthritic).

Acute lumbago, 1. (This case was too acute to determine the division to which it belonged.)

The case which was spoken of early in the paper, in which I believe that a lesion of the sacro-iliac joint occurred, was the following:

Case 12.—A healthy woman of 40, of athletic habit, in the fall of 1911 was standing bent over her dog, which she was washing. Her trunk was horizontal, and with one hand she was holding the dog, when with the other arm she reached up and to the right to get a piece of soap. Something snapped in the right side of the back low down, and when she tried to stand erect it was done with difficulty and with much pain in the right sacro-iliac region. Walking was accomplished with much pain. She had to keep rather quiet, and was treated by an osteopath for a week without relief. When she sent for me I found marked tenderness over the joint, pain in movements of the right leg, especially in walking, and a sidling gait much like that seen in tuberculous disease of the sacro-iliac joint. The back was strapped with adhesive plaster, not with any idea of fixing the sacro-iliac joint, but for the same kind of support that one would give a sprained ankle by a sticking plaster or cloth bandage. Walking was forbidden, and a tight-fitting corset made and worn day and night. More exercise was gradually allowed, followed by massage and exercises for the back muscles, and in six weeks the patient was sufficiently well to resume fancy dancing, which was her means of exercise. There has been no return of the trouble.

DIFFERENTIATION

If a case is traumatic in origin and if the sacro-iliac joints are normal in the roentgenogram and to the touch, it is to be assumed that the muscles, ligaments or joints of the spine or of the spine and pelvis have been sprained, and that the condition is similar to that of the sprain of any other joint. If the case is not traumatic in origin, lateral and anteroposterior balance are to be investigated, and static errors in the feet must be remembered as one cause of defective balance. The round back and the overfeminine figure seem especially prone to static backache, but the diagnosis of this type must sometimes be made in the absence of gross malposition.

In all cases in women the possibility of a pelvic cause must be borne in mind, and an inquiry into symptoms indicating pelvic disorder may lead to a conclusion that a competent cause for the backache exists there. The case must be classed as probably arthritic when it is chronic and there are marked stiffness and pain in motion, with muscular spasm and secondary lateral curvature. Referred pains in the legs and disturbances of sensation are suggestive. A fair-minded surgeon, however, must sometimes confess that he cannot classify the case with certainty.

The coexistence of neurasthenia or psychasthenia does not invalidate the diagnosis, and the diagnosis of hysteric or neurasthenic spine is no diagnosis at all.

PROGNOSIS

Since I have investigated and attempted to classify my cases more closely, my results and prognosis have been much more satisfactory. In balance cases I give a favorable prognosis under proper treatment unless the patient is neurasthenic, in which case I am extremely guarded and doubtful in my own mind as to the outcome. Cases clearly pelvic in origin should not be treated by the orthopedic surgeon of course; cases clearly traumatic are favorable as to prognosis except in elderly persons and in those undertaking litigation. In arthritic cases seen fairly early I look for recovery from pain with a spine more or less stiff, and I expect them ultimately to give up support.

The results in the eighty-three cases seen by me in 1912 are tabulated from my records as follows: cured, 33; improved, 10; relieved, 24; failure to relieve, 4, and no final note, 12.

TREATMENT

The treatment of the pelvic variety belongs to the gynecologist, but it must be remembered that there are often border-land or mixed cases, and that treatment of the static element may be subsequently required, and in certain mixed cases in which either the static or pelvic element may be considered a competent cause, it may be desirable to try the mechanical treatment before proceeding to operation, provided the patient is aware of the situation.

The treatment of arthritis of the spine consists in fixation of the spine, and my personal experience has led me to regard the plaster-of-Paris jacket for this purpose as uncomfortable and on the whole unsatisfactory. A canvas corset, lacing in the back, reinforced by light steel straps, has proved much more efficient and adaptable. In the severest cases a leather corset or steel back-brace may be required.

The treatment of traumatic cases does not differ essentially from that of the arthritic cases just described in the severer cases, or in the lighter cases from that of the static cases to be discussed next.

In the treatment of static cases unilateral defects in balance should be carefully studied, and if present, as shown by a lateral curve of the spine (generally slight), should be corrected by elevating one heel. Static disturbances of the feet, as shown by pronated feet or by feet with short gastrocnemius muscles, should be corrected. The general condition must be inquired into, and so far as practicable, overstrain and faulty habits of life remedied. Recumbency for part of the day is desirable in most cases, and severe cases at first should be recumbent for most of the time.

The mechanical treatment of static cases here advocated is based on the experimental work of Reynolds and Lovett, and on clinical experience. This work showed that a properly fitted corset threw the center of gravity of the body back, and that this effect was reinforced by high-heeled shoes; consequently, in cases presumed to be due to a forward displacement of the center of gravity of the body, and to resulting posterior muscle-strain, the application of a properly fitted corset is the most important part of the treatment. Muscular training might be supposed to be the first requisite, but we are dealing with overused and irritable muscles which first demand rest and support, and as a rule the immediate use of gymnastics and back-massage is unsuccessful and irritating.

The requirements of a therapeutic corset are as follows: 1. It should be tightest around the bottom, and the circular pressure should diminish from the bottom to the top, where it should be loose. In this way abdominal support is afforded and the circular constriction around the glutei, already spoken of, is furnished. 2. It should be straight in front. 3. It should support the hollow of the back. 4. It should not press forward against the back at the top. A therapeutic corset does not require heavy steels to make it efficient, but its proper effect depends on the cut of the cloth and the lines of strain, and the manufacture of such a corset lies within the capacity of any good corset-maker. Ready-made corsets may in many instances be adapted to the proper requirements. For men, a heavier canvas corset, reinforced as may be needed by light steels, is preferable to the lighter woman's corset. The heels of the shoes should in most instances be raised an eighth or a quarter of an inch. As the back quiets down, gymnastic exercises and massage of the back are desirable, and such exercises should be aimed at teaching the patient to learn to assume and to hold a more normal standing position. The electric light is often of value.

CONCLUSIONS

This paper is a plea for a careful etiologic study of each case of chronic backache or lameness of the back, and an attempt to present a classification which is very crude, but which has worked out satisfactorily in practice. Cases have been cited to show the variety of symptoms and the way in which treatment has or has not been successful. The popular diagnosis of "sacro-iliac relaxation" has been commented on, and attention has been called to the fact that adhesive-plaster straps on the skin cannot possibly "immobilize" relaxed sacro-iliac joints which at every step must bear the weight of the trunk as a downward thrust, and that the fact that treatment of this sort often relieves symptoms is fair evidence that the diagnosis in such cases in incorrect.

234 Marlborough Street.

THE USE OF CHOLESTERIN ANTIGEN IN THE WASSERMANN REACTION

CYRUS W. FIELD, M.D.
Pathologist, Pathological Laboratories, Bellevue Hospital
NEW YORK

A method of preparing a standard antigen for the Wassermann reaction is given in the Yale number of the *Archives of Internal Medicine*.[1] The advantage of the method is that at any time an antigen may be prepared that gives constant results in the reading of the reaction. This antigen is an alcoholic extract of guinea-pig heart half saturated with cholesterin; the reason for the addition of this substance is at present unknown, but it seems to stabilize the reaction.

Of late there have been a number of articles criticizing the addition of cholesterin to the syphilitic antigens, most of the authors asserting that it renders the antigen too sensitive. As a result of something more than five thousand routine tests[2] comparing the acetone insoluble antigen with this cholesterin antigen, it was found more constant and more reliable if certain fundamental conditions were observed in using it. Some workers recently have recommended the use of 1 or 1½ units of complement instead of the 2 units as used in the original Wassermann method, in order to render the test more delicate. The persons recommending this modification can have but slight knowledge of serum work, for they seem not to realize that Wassermann adopted the 2 units of complement for a very definite and, to all serologic workers, a well-known reason. The complement is thermolabile, and its exposure to a temperature of 37.5 C. (99.5 F.) for one hour decreases its activity. Therefore, if but 1 unit of complement is used, some is destroyed during the binding period and so a partial inhibition will occur without any reaction between antibody and antigen.

---

[1] Field, Cyrus W.: I ethod Developed for Obtaining a Standard Wassermann Reaction, Arch. Int. Med., May, 1914, p. 790.

[2] All patients over three days in the hospital are supposed to have a Wassermann test. From fifty to one hundred tests are performed each day, five days of the week.

The cholesterin antigen must be used with between 2 and 3 units of complement; even 4 units will reduce the reading only slightly. The presence of a native hemolysin may be ignored entirely, as it makes no difference if there be 2 or 10 units of amboceptor present, if the sheep-cells have been sensitized with hemolysin before they are added to the serum-complement-antigen mixture. These facts may be seen in Table 1. Again, with cholesterin antigen it is unnecessary to make use of the ice-box incubation of the serum-complement-antigen system as the cholesterin seems to increase the velocity of the reaction. The rule in this laboratory is to incubate the complement-serum-antigen mixture in a water-bath for not more than fifty minutes at from 35 to 36 C. (from 95 to 96.8 F.). As has been pointed out,[1] six different dilutions of the antigen are used for testing each serum. The greatest amount of antigen used is 0.1 mg., with 0.1 c.c. of the serum, plus from 2 to 3 units of complement. The second antigen tube contains 0.08 mg., the third 0.06, the fourth 0.04, the fifth 0.02 and the sixth 0.009 mg. In this way we have a series of tubes with a constant amount of serum and a decreasing amount of antigen, and if we let 0 represent complete hemolysis, 1 marked hemolysis, 2 slight hemolysis and 3 no hemolysis, we have a possible numerical series of from 0 to 18, depending on the amount of inhibition of hemolysis in this series of tubes; for complete inhibition in all six tubes would give 3 × 6 = 18.

TABLE 1—COMPARISON OF VARYING AMOUNTS OF COMPLEMENT AND AMBOCEPTOR ON A POSITIVE WASSERMANN

						Antigen Tubes					
A	B	C	D	E	O	0.10	0.08	0.06	0.04	0.02	0.009
0.1	2	2	1	16	0	3	3	3	3	3	1
0.1	4	2	1	14	0	3	3	3	3	2	0
0.1	6	2	1	8	0	3	3	2	0	0	0
0.1	2	4	1	16	0	3	3	3	3	3	1
0 1	4	4	1	13	0	3	3	3	3	1	0
0.1	6	4	1	7	0	3	3	1	0	0	0
0.1	2	6	1	16	0	3	3	3	3	3	1
0.1	4	6	1	13	0	3	3	3	3	1	0
0.1	6	6	1	10	0	3	3	3	1	0	0
	2	2	1	0	0	0	0	0	0	0	0

A = Amount of patient's serum in 1 c.c.
B = Units of complement.
C = Units of amboceptor.
D = Units of sheep red blood-cells.
E = Total number of units.
O = Control tube; no antigen.

In the series of over five thousand cases, only 0.5 per cent. have given complete inhibition in the 0.009-mg. tube. If too little serum is obtained to use in the six antigen tubes and one or two controls, we can reverse the procedure and vary the amount of serum, keeping the antigen constant at 0.1 mg. in each tube. The results of such a procedure may be seen in Table 2, and it shows well the close agreement in the final readings of the two variations. The amount of antigen 0.1 mg. is one-fifth the anticomplementary dose with the complement diluted 1:8 and using 0.5 c.c. This may be seen in Table 3. We do not find anticomplementary substances in the serum if it be poured off the clot within twelve hours after collection and centrifuged free of red cells.

TABLE 2.—COMPARISON OF POSITIVE SERUMS WITH SERUM CONSTANT, ANTIGEN VARIABLE, AND ANTIGEN CONSTANT, SERUM VARIABLE

		0	1	2	3	4	5	6	T
58	A	0	3	3	3	3	3	0	15
	B	0	3	3	3	3	3	0	15
62	A	0	3	3	3	2	0	0	11
	B	0	3	3	3	1	0	0	10
66	A	0	3	3	3	3	3	0	15
	B	0	3	3	3	3	3	1	16
67	A	0	3	3	3	3	3	0	15
	B	0	3	3	3	3	3	1	16
70	A	0	3	3	3	3	3	0	15
	B	0	3	3	3	3	3	0	15
72	A	0	3	3	3	2	1	0	12
	B	0	3	3	3	3	2	0	14
73	A	0	3	3	3	2	0	0	11
	B	0	3	3	3	3	1	0	13
75	A	0	3	3	3	3	1	0	13
	B	0	3	3	3	3	3	0	15

A = Serum constant, 0.1 c.c. antigen variable; 1 = 0.1 mg.; 2 = 0.08 mg.; 3 = 0.06 mg.; 4 = 0.04 mg.; 5 = 0.02 mg.; 6 = 0.009 mg.
B = Antigen constant, 0.1 mg. serum variable; 1 = 0.1 c.c.; 2 = 0.08 c.c.; 3 = 0.06 c.c.; 4 = 0.04 c.c.; 5 = 0.02 c.c.; 6 = 0.009 c.c.
O = Control tube, 1 c.c. serum, no antigen.

TABLE 3.—ANTICOMPLEMENTARY TITRATION

	Amounts of Antigen in Milligrams									
A	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.

With this cholesterin antigen the serum must be inactivated. The constancy of the unit readings was demonstrated in the previous paper,[1] and in Table 4 there are shown various readings on the same patient obtained at different times. A child was admitted to the hospital with amaurotic family idiocy. This child gave negative Wassermann reactions, but in its appearance suggested congenital lues. The blood from the father (B. S., a Hebrew, aged 28) was found to have 15 units. He did not accept this report and had his serum taken by a private physician, who sent it to the Board of Health; it was reported a very strong positive. Not satisfied with this, and unknown to ourselves, he came to our dispensary and his blood was again sent in to this laboratory, where it was reported again 15 units. He then went to a large private hospital in this city where he had his Wassermann taken again, and this time it was reported negative. For some unknown reason he was dissatisfied with this report and returned to our dispensary, where the blood was once more taken and sent to the laboratory and reported back 15 units. At the time these readings were made the previous reactions were unknown to us. He came to the laboratory a week after the last report, thinking that it was another institution, to have another test made. He maintained that he had never been sick and had never had a chance to contract the disease. On questioning him closely it was found that he had not been in robust health for some years, that his wife had not been well since she had married him, and that the child with amaurotic family idiocy was the youngest, the elder one (aged 6) having always been a sickly and poorly nourished infant. He was requested to bring his wife and eldest child to the laboratory, which he did. Blood was obtained from all three and the result of the tests is shown in Table 4. The child presented the appearance of a case of mild congenital lues with slightly pegged teeth. The mother stated that she had had one miscarriage at six months and one birth of a dead child at full term; that she suffers continually from headaches and is ill nourished. The husband complained for the first time of his mouth being sore; his tongue showed several typical mucous patches. With the acetone-insoluble antigen the child showed a weak positive, and the mother was negative. In Table 4 the reactions are with the cholesterin antigen.

TABLE 4.—WASSERMANN REACTIONS WITH CHOLESTERIN ANTIGEN

Wife	3/ 3/13	2
Child	3/ 3/13	11

The clinical diagnosis of syphilis may be extremely difficult and we now know that there are many cases of latent or mild lues in which the disease is not suspected, and in many cases no so-called primary or secondary lesions are observed, and these patients may give negative Wassermanns and show no symptoms leading one to suspect a diseased condition clinically. The court of last resort as to the value of the Wassermann reaction must be the post-mortem examination. In this hospital the positive Wassermanns, even when only 1 or 2 units during life, have been constantly associated at post mortem with pathologic lesions which have been recognized for years as being syphilitic. On the other hand, there have been a certain number of cases showing syphilitic lesions which have given during life a negative Wassermann. Until there is obtained a series of one thousand or more necropsies with Wassermann reactions taken during life and correlated with the necropsy findings, it is merely guesswork to state the absolute value of this reaction. We must, it seems, revise a great many of our conceptions in regard to lues. The more we study it in the light of the Wassermann reaction, the more closely does it resemble tuberculosis in its protean manifestations. Also, we must bear in mind that there are, without doubt, variations in the virulence of different strains of spirochetes and that there are variations in the resistance of individuals to the spirochete. Not until a very large series of cases has been studied in the routine manner described shall we be able to follow this disease in all its manifestations.

In conclusion, we must remain in a neutral position in the face of weak positive reactions, and in justice to the patient we should give a provocative dose of salvarsan or neosalvarsan and see whether or not the reaction is increased. In this hospital we have in several cases found it necessary to give two or even three and four full doses before being able to obtain a positive reaction in known syphilitics. In view of the possibility of these cases developing syphilitic lesions of the parenchymatous type, we must be on our guard and watch such patients very closely, since after the development of paresis there is little hope in specific therapy.

Under specific treatment the reaction slowly disappears and the serum from week to week shows a gradual drop in the number of reacting units. The reaction disappears with this cholesterin antigen much more slowly than with any of the other antigens. The statement made recently in the *British Medical Journal* that a positive reaction with this antigen means only that the patient has had syphilis and does not indicate a still active process is, in our opinion, unjustified by the facts and our observations.

First Avenue and Twenty-Ninth Street.

FATAL ATTACK OF FILARIAL LYMPHANGITIS SIMULATING BUBONIC PLAGUE

I. GONZALEZ MARTINEZ, M.D.
Director of the Biological Laboratory of the Service of Sanitation
SAN JUAN, PORTO RICO

Patient, R. P., aged 10, reported as a suspected case of bubonic plague, entered the Quarantine Hospital at noon, January 28. Two hours and a half later an examination was made by the director of sanitation and myself. From a careful observation of the symptoms, and exploration of the painful zones in the groins we concluded that the diagnosis of plague was probably incorrect; but we were convinced that the suspicions of Dr. Dobal, the attending physician, were justified; because painful glandular infarcts, suddenly appearing in the groin of persons living in tropical regions in which previous epidemics of bubonic plague have been registered, may and should be considered as suspicious, especially when accompanied by serious general symptoms, such as fever, delirium and stupor, provided that, as in this case, the patients are not affected with venereal diseases or ulcerative or inflammatory processes of the inferior extremities.

General Examination.—The child was seriously ill. He was lying in a dorsal decubitus with the right thigh flexed on the abdomen, unconscious and stuporous; the expression in the eyes was vague and irresolute, and in answer to questions only whispered incoherent phrases were elicited. The pulse was uncountable, the temperature exceeded 39.5 C. (103.1 F.), subsultus tendinum almost continuous and a quiet delirium gave evidence of the exhaustion of cerebral centers now thoroughly intoxicated. There was involuntary emission of much dark and fetid liquid fecal material. Locally we observed only two small glandular infarcts in the region of the right groin, which were excessively painful on palpation, and pressure no matter how light, awakened the patient from his stupor, and caused him to complain and sometimes to cry out. The patient was in fact overwhelmed by the fierce onset of some virulent toxin, and was quietly succumbing to the inevitable narcosis of death.

The manner of onset of the attack, with strong chill, hyperpyrexia, thirst, and later vomiting, all rapidly followed by delirium, stupor, and profuse diarrhea, clinically excluded the diagnosis of any ordinary form of bubonic plague in spite of the intense pain localized in the region of the right groin and the hardly perceptible infarct of the inguinal glands. To those accustomed to follow the course of plague, there was no possible confusion except with septicemic forms with poor reaction. But in such case, the experimental inoculations, etc., would openly resolve all doubts. On the contrary, the sudden attack, the suggestive history of its progress during the preceding twenty-four hours and the suspicious syndrome presented, impressed on our minds the belief that we were facing a case of pernicious filarial lymphangitis. I was informed afterward that the same suspicion had passed through the minds of Drs. Gutierrez Igaravidez and Zavala, who independently and on different occasions examined the case.

We felt obliged therefore to conduct our investigations with both possibilities in view, because the etiology and pathogenic problems had exceptional importance from the sanitary point of view as well as for that affecting the nosography of the country.

Urinary Examination.—A specimen of the patient's urine (100 c.c. obtained by catheter) was examined at the biological laboratory, Mr. J. Loubriel performing the chemical analysis, and I the microscopic examination of the sediment. In the dense and reddish urine, specific gravity 1.024, Loubriel discovered only traces of sero-albumin, but in the sediment I verified the presence of the following histologic elements: fairly numerous erythrocytes, a number of leukocytes in proportion to the frequency of red corpuscles, fairly numerous epithelial cell of the tubuli contorti, some of the renal pelvis, a moderate number of hyaline casts, a few finely granular casts, fairly numerous irregular crystals of uric acid, and a most unique and interesting find: lying near one of the edges of the preparation there appeared a beautiful specimen of Lewis and Manson *Microfiliaria nocturna*, embryo of *Filaria bancrofti*, confirming the tentative clinical diagnosis which we had made. All the operations were accomplished with exquisite cleanliness from the moment of the catheterization up to and including the microscopic examination of the sediment.

Blood Examination.—The presence of the filarial infestation did not, however, exclude the possibility that the pernicious lymphangitis might be a local syndromic expression of septicemic plague. Specimens of fresh blood were therefore collected from the patient at 9 p. m., January 28, and examined at 8 a. m. next day. We succeeded in confirming the presence of numerous embryos of the *Filaria nocturna* in the fresh specimens of peripheral blood.

Meanwhile the patient had died at 3 a. m. the same morning, during the coma and subnormal temperature following a period of delirium, convulsions, and hyperpyrexia of the afternoon and evening before.

Necropsy.—This was begun at 9 a. m. by Dr. Hernandez and myself, and lasted three hours. Specimens taken for histologic study were preserved, part in 90 or 95 per cent. alcohol and part in Zenker's fluid.

The subject was a child well constituted, apparently aged 12, and without any sign of traumatism of the skin, or ulcerated lesions of the trunk, or extremities. The post-mortem rigidity was complete, and lividity had begun to appear in several places, but principally in the inguine-abdominal region of the right side. This zone during life was the only location wherein there were local manifestation of pain and inflammation which would give rise to a reasonable suspicion of Yersinian infection as maintained at first by Dr. Dobal. Furthermore, in this region Dr. Hernandez had punctured a gland in seeking the necessary material for a bacteriologic diagnosis.

When exposed by dissection the cluster of glands in Scarpa's triangle as well as the inguinal group appeared intensely red and congested, some of them larger than normal, all lightly enveloped in a gelatinous substance, and on section exuded a transparent lymph. The redness and congestion and the lymphatic flow continued under Poupart's ligament along the line of the iliac vessels into the abdominal cavity. The right and left ganglionic group were dissected out and preserved, half of each being placed in alcohol, and the other half in Zenker's solution.

The lungs, heart and pericardium appeared normal. The thymus was very large. The right lung was removed, and blood-smears obtained from the parenchyma, specimens of which, removed from the vicinity of the hilum and from the lobules, were also preserved for future histologic study. Cultures and smears were made of the heart's blood. The hypertrophied thymus was extracted whole, divided into small pieces, and preserved. The liver, pancreas and spleen presented a normal color, but the kidneys were congested and enlarged, the mesenteric gland enlarged, and the retroperitoneal glands red, infarcted, infiltrated, and covered with an edematous cellular tissue. After resecting the gall-bladder, previously ligating the cystic duct and tributary vessels, in order to make cultures of its contents in the laboratory, we removed several fragments of the liver, which weighed 830 gm.

The spleen weighed 50 gm. Specimens of splenic pulp, obtained with aseptic precautions, were used to inoculate culture mediums. Another fragment was rubbed over the skin of the abdomen of two guinea-pigs, previously dry shaved and lightly scarified. Specimens of this organ and of the kidney and suprarenal capsules were also placed in the preserving fluid.

The dissection of the retroperitoneal glands was hastily done, owing to the advanced hour. Not being able to stop to make a minute and prolonged investigation, as would have been necessary in order to find and separate the harboring places of adult parasites, we limited ourselves to gathering the largest possible number of glands and their lymphatics, which we preserved in Zenker's fluid and alcohol. The same practice was adopted with reference to the mesenteric glands.

While Dr. Hernandez and I were advancing with our work of the necropsy, Dr. Gutierrez Igaravidez was rapidly examining a number of smears from the lung and heart, stained by the Romanowsky method, in all of which he found numerous microfilaria. While the slides from the lungs were literally crowded with embryos, those smeared with the blood of the heart exhibited a very considerable diminution in number.

The results of the bacterial and experimental investigation obtained with the specimens secured *intra vitam* and during the post-mortem examination were as follows:

1. The microscopic examination, made by Dr. Hernandez, demonstrated the absence of bipolar staining bacilli in the glandular substance, in the blood of the great vessels, and in the fluids of the viscera.
2. The incubation and the careful inspection, also attended to by Dr. Hernandez, of the special mediums inoculated for the purpose of bacteriologic diagnosis of the plague, were also absolutely negative.
3. The experimental inoculations of the guinea-pigs with the glandular fluids, *intra vitam*, and with the splenic pulp, taken post mortem, hypodermically in the former case, and by way of the skin in the latter, produced no alteration in the physical condition of the animals, and, therefore, after seven days must be considered negative.
4. The cultures made by us with the different culture mediums to ascertain if other micro-organisms were present in the blood of the heart, and in the contents of the gall-bladder, proved to be sterile after several days of incubation at 37 C.
5. The cultures of splenic pulp rapidly developed as typical colonies of *Bacillus coli communis*.

CONCLUSIONS

1. The patient died within a period of thirty-six hours from some pernicious paroxysm which was not of malarial origin.
2. The disease which caused this rapid death cannot be confounded, in spite of the painful adenitis of the right inguinal region, with one of the common forms of bubonic plague.
3. Such confusion could have been possible only with the septicemic form.
4. In case of a plague septicemic an early necropsy would have dispelled all doubts and thus fixed on the right diagnosis.
5. The clinical syndrome, and the unusual violence of the attack, inclined us to the theory of an endemic pernicious lymphangitis rather than of a plague septicemia.
6. My finding the embryos of *Filaria nocturna* in the urinary sediment of the patient was of value as confirming the theory.

7. The presence of a great number of microfilariae in the blood of the peripheral circulation, demonstrated in blood collected during the night, and confirming the findings in the analysis of the urine, proved without doubt the diagnosis of a filarian infestation.

8. The presence of a filariasis, however, did not exclude concomitant plague septicemia.

9. On this supposition the necropsy was the only means of resolving the doubt.

10. The lack of any visible pathologic alterations in the viscera, and especially in the spleen, liver, and lungs, dissipated all ideas of it being any form of bubonic plague.

11. The absence of Yersin's bacillus in the microscopic preparations obtained from the glandular fluids, *intra vitam*, and of the visceral pulp, post mortem, excluded definitely the probability of its being plague.

12. The entirely negative results of the experimental inoculating of guinea-pigs *intra vitam*, with the glandular fluids, and post mortem with the splenic pulp, and the failure of microbian colonies to develop in the mediums especially prepared from both, also definitely excluded the diagnosis of plague.

13. The absence of streptococci or staphylococci, and of all bacillary forms in the blood of the general circulation taken from the heart, excludes furthermore any such bacteriemia caused by aerobic microbes.

14. The presence of colon bacilli in the splenic pulp lacks importance and has no pathologic significance in this case, because it is a microbe which normally invades the organs, and especially the spleen a few hours after death. It must be taken into account, furthermore, that the necropsy was commenced six hours after death, and if this micro-organism had been in movement it would also have been found in the blood of the heart, and in the contents of the bile bladder.

15. Logically, therefore, according to the findings in the anatomico-pathologic examination, and the result of the bacteriologic investigation, the only real cause of the death of the child that can be accepted is endemic pernicious lymphangitis of filarial origin.

16. This fact has exceptional importance for the nosography of the country, because contrary to the general opinion of many investigators it proves (providing no other cause for the death can be found) that certain forms of filarial lymphangitis, without the assistance of other complicating micro-organisms, may *per se* rapidly kill their host.

17. It is also important because it shows the occurrence in Porto Rico of those grave and pernicious forms of tropical lymphangitis of filarial origin described by the Brazilian authors under the name of endemic lymphangitis, and by Mazaé-Azema, of the Ile de la Réunion, by the name of generalized intraganglionar lymphangitis.

Still more important is the fact that our diagnosis may be sustained without objection. If it is true, as the Brazilian authors and the physician of the Ile de la Réunion have it, that endemic plague exists in both countries, the lack of bacteriologic diagnosis would inevitably cause confusion between a typical form of plague and serious cases of elephantoid fever, whereas, in our case, this argument may be thrown aside, because the complete study, both microscopically and bacteriologically, ante mortem and post mortem, accomplished by competent and experienced physicians, and following procedures established in the laboratory for the diagnosis of bubonic plague, is the base on which I support my contention.

DISEASES CONNECTED WITH MECKEL'S DIVERTICULUM

WITH ESPECIAL REFERENCE TO DIVERTICULITIS *

J. P. CROZER GRIFFITH, M.D.
Professor of Pediatrics in the University of Pennsylvania
PHILADELPHIA

There occurred in my practice not long ago a case in which the combination of clinical manifestations and pathologic lesions was so unusual, so unexpected, and so misleading that it seems worthy of being recorded. It belongs in the category of diverticulitis, but seems almost unique in some respects. At least I have failed to find any case on record giving just the same symptom-complex.

Joseph C., aged 19 months when first seen by me, March 15, 1912, had been in good health and well nourished until in the preceding summer, when he suffered from a condition which his physician called "auto-intoxication," although he later spoke of "scurvy." Possibly both disorders had been experienced. He recovered and remained well until November, 1911, when he had a fall down stairs, but apparently without discoverable serious injury. A week later he began to suffer from slight attacks of indigestion. Early in January, 1912, the mother was alarmed to find on one occasion that the formed stool which the baby had passed was of a partly reddish color, and that when put into water it stained it a deep red. Previously to this there had been some constipation. The bowels now remained normal and without constipation for two weeks, when another reddish stool was passed similar to the one described. The child suffered also from attacks of abdominal pain which were supposed to depend on indigestion. February 16, he had an attack of complete suppression of urine lasting for over twenty-four hours. Catheterization showed the bladder to be empty. He then urinated very little for almost a week. There had been some slight drowsiness before the attack. There was no edema or nervous symptoms of any sort. At this time the mother noticed the change in the child's appearance, the former healthy tint having been replaced by a waxy whiteness which never afterward improved. After recovery from the suppression and oliguria, the attacks of paroxysmal abdominal pain continued to occur with greater frequency and constantly increasing severity, the child, when suffering most, often lying on the abdomen with the knees drawn up under him. Occasionally there was vomiting of thickly curdled milk. Constipation became troublesome, and bowel movements were obtained only by the use of purgatives, the expulsion of feces being accompanied by much flatus. A Philadelphia pediatrist was called in consultation, and made the diagnosis of anemia, which a blood-examination showed to be apparently of a secondary nature. Nothing was said to the parents of the importance of the blood-colored stools. Probably the existence of such stools had not been mentioned by them. Repeatedly since the attack of suppression the feces had been of a liver-color or a reddish brown. Nosebleed had occurred once a few days before I saw him.

At the time of my first visit the baby was in a dull mental state, looked very ill and was strikingly pale, but was without edema or evident wasting. Abdominal pain was severe, and the abdomen moderately tympanitic and tender. Just before the visit there had been passed by rectum a small dark-red blood-clot the size of a pigeon's egg, and the child had also vomited. The great weakness of the patient prohibited satisfactory examination, and the only diagnosis possible seemed to be that of secondary anemia dependent on repeated, or, perhaps, almost continuous, intestinal hemorrhage, generally of small amount at any one time. The cause of the hemorrhage was not certain, but ulceration of some portion of the intestinal tract seemed probable. The pain appeared to depend possibly on the tympanites, although this explanation was not entirely satisfactory. The significance of the attack of urinary suppression was not at all clear.

---

* Read before the American Pediatric Society, May, 1914.

March 16: There had been three or four intestinal hemorrhages of considerable size during the preceding night accompanied by much abdominal pain. The child was seen with me on this day by Dr. J. H. Jopson, attending surgeon to the Children's Hospital of Philadelphia, who could discover no rectal disease or anything abnormal in the abdominal cavity, although the tympanites prevented to some extent a satisfactory investigation. The question of exploratory laparotomy was discussed, but the uncertainty of the diagnosis and the extremely weak condition of the patient made this seem inadvisable. A 10 per cent. gelatin solution was given freely by the mouth, albumin-water prescribed as the diet, and laudanum in 2-drop doses ordered as demanded by the pain. A hypodermic injection of 2 c.c. of horse-serum was administered by Dr. John Speese, in the effort to control the hemorrhage.

March 17: An examination of the blood made on this date by Dr. John Diven showed very rapid coagulation on puncture, a hemoglobin percentage of 22, red blood-cells 1,590,000, and leukocytes 7,840. The differential count (300 cells) gave polymorphonuclears 76 per cent., small lymphocytes 14 per cent., large mononuclears 5 per cent, transitionals 3 per cent., eosinophils 1 per cent, and basophils 1 per cent. There was poikilocytosis, but no nucleated red cells were found. The examination of the urine made by Dr. C. A. Fife showed a specific gravity of 1.016; acid reaction; no albumin or urobilin; trace of indican; uric acid and phosphate crystals, no casts or red or white blood-cells.

March 20:: There had been no return of hemorrhage, and the pain was better, without need for the laudanum. The general condition, likewise, had improved. The bowels had been opened daily by saline douches.

March 22: The child was very much better, and was sitting up out of bed.

March 27: Two days previously there had commenced a serious relapse in the condition of the patient, and the pain had been extremely severe; more than could in any way be accounted for by the tympanites. Some slight evidence of blood had appeared in the stools. Castor oil was administered on the day previous, and a very large mass of cheese-like consistency was passed, of a most offensive odor but apparently not containing blood. The child died exhausted on the 27th. During the attack there had been a moderate irregular febrile reaction.

The final clinical diagnosis was that of secondary hemorrhage depending on ulceration somewhere in the intestinal tract. The cause of the severe pain was not clear. A necropsy was made by Dr. Howard C. Carpenter, whose report reads as follows:

"On opening the abdomen a localized peritonitis was seen just below the umbilicus. This localized peritonitis could have been placed in a circle having a diameter of 8 cm. In this area four coils of intestine were firmly matted together, and the serous coat of the bowel showed a fibrinous peritonitis. When the coils were forcibly separated an abscess was discovered which contained a little more than 2 drams of pus. Further dissection allowed the pus to escape and revealed a Meckel's diverticulum in the center of the abscess-cavity. The diverticulum measured 3 cm. in length, and its walls were quite thick, averaging about 8 mm., but thinner at the tip. It was firm on palpation, giving the sensation characteristic of a chronic inflammatory process. The mucosa of the diverticulum was swollen and eroded, and at the tip of the organ there was found an ulcer 8 mm. in diameter. The opening between the ileum and the diverticulum was small but patulous. The distal extremity of the diverticulum was free. There was a purulent exudate at its tip on the serous surface, corresponding in location to the ulcer on the mucous surface. The remainder of the intestine, including the appendix vermiformis appeared normal. The mesenteric glands were somewhat enlarged but without evidence of suppuration. The liver was normal in size but yellowish in color, showing a fatty infiltration. There were no metastatic abscesses discovered. The spleen was normal. The kidneys showed an acute diffuse nephritis. They were moderately enlarged and red in color, with a wide cortex containing reddish streaks."

We have here, then, probably primarily an ulcerative inflammation of Meckel's diverticulum which was the cause of the persistent leaking of blood from the bowel, and of the severe anemia. As time elapsed, this inflammation extended to the serous layer of the diverticulum, producing a secondary, purulent peritonitis, localized by the matting of the coils of the ileum around the seat of suppuration. The severe abdominal pain was due to this peritonitis, and in part, perhaps, to the kinking of the intestine, making evacuation of the bowel difficult, and accounting for the constipation. The origin and bearing of the nephritis was uncertain. It appeared to have had little part in the final complex of symptoms and the fatal termination.

Meckel's diverticulum, the remains of the omphalomesenteric duct, although bearing the name of this investigator, was in reality, according to Fitz,[1] known earlier, being illustrated by Ruysch[2] in 1701. The organ may cause disease in various ways. The subject has been studied in its various aspects by numerous writers, among whom I may mention Rayer,[3] Fitz,[1] Kelynack,[4] Payr,[5] Hilgenreiner,[6] Porter,[7] Bunts,[8] Turner,[9] Clogg,[10] Forgue and Riche,[11] Gray,[12] Carnett,[13] Drummond,[14] Hertzler and Gibson,[15] and Wellington.[16] I shall, therefore, make no attempt at any exhaustive reference to the literature of the subject with details of reported cases.

None of the affections of Meckel's diverticulum appear to be of common occurrence, although a persistence of the organ in some form is found in from 1 to 2 per cent. of all persons. Thus Kelynack[4] found the diverticulum present in 13 out of 1,248 subjects examined (about 1 per cent.); the committee of the Anatomical Society of Great Britain and Ireland[17] 16 times in 769 bodies (a little over 2 per cent.); and Mitchell[18] 39 times in 1,635 bodies. Hilgenreiner[6] gives statistics on 4,848 necropsies, reported by a number of investigators, with 90 having diverticula, about 1 in every 54 persons; and Bienvenue[19] in a similar manner analyzed a series of necropsy-statistics and found 126 instances of the persistence of Meckel's diverticulum in 9,672 necropsies, or 1.7 per cent. The organ is present much more frequently in males. Of Mitchell's[18] 39 cases, 34 were in males. In Turner's[9] 145 cases in which the diverticulum was merely a postmortem finding, without pathologic alteration, the distal extremity was attached to some region in only 9 instances. On the other hand, in 161 cases with pathologic changes it was attached in 110.

As a rule, the presence of Meckel's diverticulum gives rise to no symptoms whatever, and this is particularly true, as just pointed out, when it lies distally free in the abdominal cavity. A number of series of cases have been published, however, in which the organ occasioned symptoms of disease. Thus Porter[7] details 184 collected reports of cases of disease of the diverticulum, although he found others on record with too meager a description to render them of value for study. Forgue and Riche[11] collected 287 cases of intestinal obstruction by Meckel's diverticulum, and Wellington[16] 326 cases of disease of the organ. The largest series of reported cases of pathologic conditions of the diverticulum appears to be that by Rostowzew[20] of 634 cases. I have not had access to his original publications.

Lesions due to Meckel's diverticulum seem oftenest to produce symptoms in adult life, the average age of Porter's[7] patients being 21 years and 9 months. Bienvenue,[19] however, thinks that the greatest number of pathologic changes occur in childhood. Males are more frequently affected than females; in 265 of Wellington's[16] cases in which the sex was mentioned, there were 201 males and 64 females.

1. The most frequent lesion found is *strangulation of the intestine by the diverticulum or its remains,* usually attached to the umbilicus or to some part of the intestine, mesentery or other region. In cases of obstruction by Meckel's diverticulum, Hilgenreiner[6] found the organ attached distally in the proportion of about 4 attached to 1 free, with the attachment most frequently to the mesentery. The diverticulum may either be in the form of a fibrous, cord-like remainder of the organ, or have its lumen still present, through all or a part of its extent. In either case the ileum becomes ensnared in various ways, causing constriction and strangulation. Although a considerable number of such cases are reported in medical literature, the lesion is yet uncommon enough to produce probably a sensation of surprise in any physician discovering it. My own experience is limited to a single case made certain by necropsy. Of Porter's[7] 184 cases of obstruction by Meckel's diverticulum, 101 were due to the presence of a constricting band; and this was true, likewise, in 144 of Wellington's[16] 326 cases, not including intussusception of the diverticulum or volvulus.

The symptoms are those characteristic of most varieties of intestinal obstruction, with the exception of ordinary ileocecal intussusception, and it is only by operative interference or at necropsy that the diagnosis can be made with certainty. Intestinal obstruction due to this cause may occur in early life or later. There has been a division of opinion as to which period is more common. Forgue and Riche[11] and Hilgenreiner[6] agree that the most frequent age is from 15 to 25 years, and the weight of opinion seems to be in favor of this view. It is estimated by Halstead,[21] on the basis of 991 collected cases of strangulation of the intestine from different causes, that 6 per cent. are dependent on Meckel's diverticulum. On the other hand, of the 669 cases of obstruction by bands occurring in the London Hospital during 13 years (Barnard[22]) but 21 (3.14 per cent.) were due to the diverticulum.

It is to be remembered that strangulation of the ileum by a Meckel diverticulum is in a way retroactive, and the diverticulum in its turn, if it has retained its original character, may become strangulated by the ileum.

2. Another condition, properly a malformation, and naturally always congenital, is the persistence of Meckel's diverticulum with an *opening at the umbilicus.* This is unusual, and the subjects are nearly always males. Wellington[16] found but 21 instances in his 326 cases of disease of the diverticulum. Strasser's[23] statistics included a larger number, 63 in all. The lesion results in a fecal fistula through which feces may be discharged, or even, as in some reported cases, intestinal worms. The mucous membrane of the diverticulum protrudes at the umbilicus, forming a tumor, generally small, sometimes of larger size. The fistula is single and centrally situated, or sometimes, if the tumor is very large, there are two lateral openings. Occasionally, the intestine may protrude and become strangulated. Sometimes a persistent Meckel's diverticulum is obliterated near the intestine, and in this event mucus, but no feces, is discharged from the fistulous umbilical opening.

3. Among other unusual conditions sometimes found is the *formation of a cystic tumor,* the diverticulum being obliterated at both ends, as in the cases reported by Fox[24] and by Cawardine.[25] In the latter there was a cystic dilatation of the diverticulum in a new-born infant, filled with meconium.

4. *Concretions* of smaller or larger size may be present in the diverticulum. This was well illustrated in the case of Beach[26] in which there was a fecal concretion the size of a pigeon's egg, with communication through the diverticulum between the intestine and the bladder. In a necropsy reported by Sherren,[27] many small black calculi were found in the diverticulum. Similarly, as in the case of the appendix, foreign bodies of various sorts have been reported present.

5. A very unusual condition is described by Bland Sutton[28] in which there is a *superinvolution of the diverticulum,* as a result of which narrowing of the intestine is produced, the obliterative process in the diverticulum having passed beyond this region to the ileum.

6. In other cases a stenosis of the ileum may be caused by *traction* of a short diverticulum attached at its distal extremity or elsewhere.

A Meckel diverticulum persisting as a short, free organ may give rise to trouble in various ways:

7. Here is to be mentioned the rare *invagination of the diverticulum,* which is very liable to be followed by an ileocecal intussusception. Cheyne[29] collected reports of 16 cases of such intussusception. Twenty of Porter's[7] 184 cases were intussusception, and 59 of Wellington's[16] 326. Hertzler and Gibson[15] have recently published a careful review of the subject with the details in abstract of 41 collected cases, omitting others not sufficiently well-reported to permit of study The average age was 13 years, in sharp contrast to the early age at which simple intussusception of the bowel usually occurs. Inasmuch as the invagination of the diverticulum takes place on the lateral aspect of the

ileum, it may not occasion complete obstruction, but merely project into the lumen of the bowel and cause hemorrhage. This hemorrhage is usually slight, and there are none of the symptoms of diverticulitis pointing to this disorder. In other cases intussusception of the bowel promptly follows that of the diverticulum.

8. Still less common than intussusception is *volvulus of the diverticulum, or of the ileum,* depending on the presence of this organ. But 8 of Porter's[7] 184 cases were of this nature. Wellington[16] gives in 326 cases 9 of volvulus of the intestine dependent on Meckel's diverticulum. Very rarely there may be volvulus of the diverticulum without twisting of the bowel. This was seen, for instance, in a case reported by Fox,[21] and in one by Taylor.[30] Cawardine's[25] case of cystic dilatation already mentioned was produced by a volvulus of the base of the diverticulum occurring during fetal life. Volvulus of the diverticulum or of the ileum is more liable to take place if the distal extremity of the diverticulum is attached.

9. *Hernia of the diverticulum* is occasionally seen. This has been studied by Ekehorn,[31] who collected 22 cases, and later by Gray,[12] who has a list from literature of 42 cases. There were others found by Gray, making the number 60 in all, but too briefly reported to be of value for study. Thirty of his cases were inguinal and 12 femoral. The average age was 37 years.

10. *Inflammation of Meckel's Diverticulum* — the subject under special consideration in this contribution — appears to have first been named "diverticulitis" by Blanc[32] in recognition of the analogy which it bears to appendicitis. The first case on record, according to Bienvenue,[19] appears to have been reported by Littré[33] in 1700. The subject has secured meager consideration or none at all in such text-books on medicine or pediatrics as I have consulted. A number of special contributions, however, have appeared in periodical literature or in theses treating solely or largely of this condition. I may refer especially to the theses of H. Blanc,[32] Bienvenue[19] and Ketteler,[34] the volume of Forgue and Riche,[11] and the periodical contributions of Clogg,[10] Rebentisch,[35] Hilgenreiner,[6] Denecke,[36] Meyer,[37] Cahier[38] and Hübschmann.[39] Some of the other writers already mentioned have discussed it to a limited extent.

The condition is one of the more infrequent abdominal diseases depending on Meckel's diverticulum. Ketteler[34] (1900) found 5 cases of diverticulitis; Denecke[36] (1902), 9; Rostowzew[20] (1902), 45; Porter[7] (1905), 17; Cahier[38] (1906), 39; Forgue and Riche[11] (1907), 59; Bienvenue[19] (1912), 40, and Wellington[16] (1913), 50. The variation in the reports depends in part on the date of publication, and in part on the limitations placed by the authors. It is interesting to note the relative tendencies, respectively, of the appendix to exhibit inflammation, and of the diverticulum to produce obstruction. Thus Leichtenstern[40] could collect but 36 cases of occlusion of the intestine by the appendix, while he found 70 cases of occlusion by the more rare Meckel's diverticulum. Inflammation of the appendix, on the other hand, is one of the most common disorders, while that of the diverticulum is of very exceptional occurrence.

The distinction is to be made at the outset between primary and secondary diverticulitis. In the latter some other lesion develops first, as when the diverticulum constricts the ileum and is in turn constricted by it, with consequent inflammation, or as when the diverticulum is strangulated in a hernial sac. In the matter of primary diverticulitis a further distinction is to be made between acute and chronic or recurring cases, and the relationship of diverticulitis to obstruction of the bowel is to be studied. Bienvenue,[19] the author of one of the latest and, perhaps, of the most extensive discussion of diverticulitis, gives as instances of chronic inflammation of the diverticulum those cases in which adhesion of the distal end of the diverticulum elsewhere than the umbilicus has at some previous time formed, as a result, he believes, of an earlier localized inflammation. On this basis he considers that the majority of instances of intestinal obstruction by the diverticulum acting as a constricting band are to be viewed as secondary to diverticulitis. Others, however, among them Forgue and Riche,[11] do not consider that these abnormal adhesions are necessarily or even usually the result of an earlier inflammation. However this may be, the chronic and the acute diverticulitis as now under consideration are quite different from this condition and are rarely the cause of a complete intestinal occlusion.

The *causes* of diverticulitis are obscure. Infection, of course, lies at the basis of the lesion. Previous digestive disturbances appear to have some bearing, and trauma, too, has seemed to have been causative in several instances, as in those of Hübschmann,[39] Kramer[41] and a few others. It should be remarked, however, that Hübschmann does not consider his case an instance of primary inflammation of Meckel's diverticulum, but of the formation of a peptic ulcer in it, following a fissure produced by the trauma, with subsequent perforative peritonitis. The influence of foreign bodies is uncertain. They have been found in a number of instances; but, as with appendicitis, they are not necessarily the cause of the inflammation. This is true also of the occasional discovery of intestinal worms in the diverticulum in cases of inflammation. Cahier[38] found foreign bodies present in 9 of 29 collected cases. Although the disease can occur at any age, the larger number appear to have developed after childhood is passed. Meyer[37] places the age of the majority of patients at from 35 to 70 years, and of Cahier's[38] 36 patients, 16 were from 20 to 54 years of age, one-third of the number being children.

From the point of view of *pathology,* diverticulitis is analogous to appendicitis, and no detailed description of the lesion is necessary. As in appendicitis, all grades of inflammation exist, extending from a mere catarrhal process to gangrene and perforation with localized or general peritonitis. There may be perforation from ulceration without gangrene. This is oftenest the result of typhoid fever. Wellington[16] collected 6 instances of this occurrence, and 2 from trauma. Makins[42] found a diverticulum with 13 perforations. Ulceration from any source is uncommon.

The *symptoms* vary to a certain extent within wide limits. Cahier[38] found 10 chronic cases with acute recurrence out of 37 instances of diverticulitis. In these more subacute or chronic or recurring cases there exist before the final crisis evidences of gastric disturbances, constipation and recurrent painful attacks oftenest in the region to the right of the umbilicus or in the right iliac fossa. In the primarily acute cases, or in those with an acute development consecutive to the more chronic condition, the symptoms so closely simulate those of acute appendicitis that the diagnosis of the latter condition is generally made. The earliest stages of the disease may be entirely without clinical manifestations. In well-developed cases the symptoms consist in severe abdominal pain, which is liable to be higher and nearer the umbilicus than in appendicitis; abdominal tenderness and resistance, and finally, dulness on percussion in this region; nausea and vomiting; fever and leukocytosis. Constipation is a frequent symptom, but diarrhea is as often seen. In a few cases of a subacute or chronic nature, such as those of Hilgenreiner, Hübschmann,[39] Meyer,[37] and my own, passage of blood from the bowel took place. My own case was most unusual in that the intestinal hemorrhage was for a time the most marked symptom, and was certainly one of the decided causes of the fatal ending. Finally, in diverticulitis there may develop the symptoms of a general peritonitis, as in cases of appendicitis. This is more liable to occur than in the latter affection. The question of intestinal obstruction as a symptom of diverticulitis has already been referred to. It is possible that obstruction may become complete from the compression of the intestine, if the diverticulum is distally adherent, or from inflammatory adhesions or kinking, or in other ways. This is, however, exceptional. More or less difficulty in the evacuation of the bowels is liable to occur in any case of diverticulitis, either from the mere kinking of the coils of the intestine involved in a localized peritonitis, or as a result of paralysis of peristalsis, as seen sometimes in appendicitis. How important a factor the latter may be is uncertain. Cahier,[38] for instance, believes thoroughly in its existence, while Meyer[37] thinks that it plays little part. In cases of secondary diverticulitis, complete obstruction may first take place, and later evidences of diverticulitis may develop, finally with localized or general peritonitis.

The question of the *diagnosis* of diverticulitis is of great interest. Is such a diagnosis possible? It is to be noted that the lesion has never been correctly diagnosed during life, although in a case reported by Karajan[43] it would seem that this might have been made. In this instance there were the symptoms suggesting appendicitis, but occurring in a man who had had in infancy up to the age of 3 years a fistulous opening of Meckel's diverticulum at the umbilicus. In general, the study of diagnosis leads mostly to discouragement. Certainly, at least, the effort to come to a correct conclusion should be made. The fact that the localized inflammation of a diverticulitis is situated most frequently in the lower part of the abdomen and toward the right makes the diagnosis of appendicitis more probable; and, as a matter of fact, most cases of diverticulitis have been thus diagnosed, and the true condition discovered only at operation. In a case reported by Hilgenreiner[6] both diverticulitis and appendicitis were present. The origin of the diverticulum, oftenest at from 1 to 3 feet above the cecum, and its attachment to a freely movable portion of the intestine, make its position in the abdominal cavity a very variable one, and the localization of symptoms is consequently subject to no fixed rule. In the cases of secondary diverticulitis in which complete intestinal obstruction has already occurred, the development of inflammatory symptoms is suggestive but not conclusive, since any form of intestinal obstruction may be followed by signs of peritoneal inflammation. The presence of blood in the stools, although of rare occurrence, is when present, suggestive of diverticulitis; yet this, too, is not conclusive, inasmuch as the symptom is in no way pathognomonic. The diagnostic features as based on the cases reported by different writers may be summarized as follows:

1. Localization of the pain and tenderness not so often at McBurney's point as somewhat higher and to the right of the umbilicus, or even about it, or in some entirely different region.
2. An area of puffiness or of firm resistance in this region.
3. Absence or slight degree of meteorism, at least early in the attack.
4. The presence of blood in the stools and in the vomited matter.
5. The earlier existence of an umbilical fistula, or of some malformation elsewhere in the body.

As regards the *prognosis,* it is impossible to reach accurate conclusions, owing to the fact that catarrhal diverticulitis, recovering, has never been recognized during life; and it is impossible to determine how often such a condition has existed. That a diverticulitis of this sort with recovery does actually occur is shown by operations and necropsies in which evidence of former inflammation has been found. The prognosis of acute severer cases is unfavorable. Cahier[40] found a mortality of 65 per cent. in 35 cases, all those patients recovering having been operated on. In 50 cases of Forgue and Riche's[11] list the mortality was 53 per cent. Wellington[16] estimated the mortality at 40 per cent.

Little need be said of treatment. The only legitimate one is operative. Inasmuch as even a healthy diverticulum is a much greater and more constant menace to life than an appendix in a similar condition, a Meckel diverticulum found in the course of an abdominal operation should be removed.

1810 Spruce Street.

Vaccination in New York—In order to form an idea as to how well the population of New York has been vaccinated, surveys were made of various groups in different sections. Information thus obtained regarding 12,437 persons shows that 12,096, or 96 per cent., had been vaccinated. The average time which had elapsed since the last vaccination was eleven years. Fifty persons, or .04 per cent., had had small-pox and 378, or 3 per cent., had never been vaccinated. Schoolchildren are well protected by vaccination which is required by law. Children under school age, however, constitute a large proportion of the unvaccinated. Of a total of 1,580 children inquired about, 291, or 18 per cent., had never been vaccinated. In a negro tenement block 35 per cent. of the children under school age had not been vaccinated. A campaign has been set on foot to secure more complete vaccination of the entire population.

45. Karajan: Wien. klin. Wchnschr., 1901, xiv, 714.

nerves of the lower extremity. They found that the tolerance was greatly increased by injecting the fluid slowly (over a period of from ten to fifteen minutes). Nevertheless, toxic symptoms appeared in a few of their cases. It was stated in the preceding paragraph that trauma to the brachial plexus may have caused the collapse of the patient. There can be little doubt of a certain amount of injury from injecting from 10 to 20 c.c. of fluid into a close-meshed plexus of nerves. It is well known that external violence applied to the brachial plexus sometimes results in a symptom-complex similar to that of my case. Despite these suggestions for the traumatic origin of the symptoms, it does not appear at all probable that injury was the cause of the manifestations. Were it so, collapse symptoms would be frequently observed. Besides, it is difficult to conceive the trauma profound enough to result in the symptoms in question. If all the fluid were injected into a single nerve-trunk, the trauma would possibly have been sufficient; the complete anesthesia of the arm, however, indicated that fluid was injected about several of the nerves. I must therefore conclude that the collapse of the reported patient was most probably due to acute novocain-poisoning, although trauma cannot be absolutely excluded as the cause.

From the experience of others and my own limited trial of the method it may fairly be stated that supraclavicular anesthetization of the brachial plexus will prove an exceedingly valuable addition to the methods of regional anesthesia when serious complications from its administration can be eliminated.

BEST METHODS OF DISCOURAGING THE ACTIVITY OF INOPERABLE CANCER

A STUDY OF HEAT IN CANCER *

J. F. PERCY, M.D.
GALESBURG, ILL.

Among the earliest of the various procedures used in the treatment of malignant growths is the Chian turpentine advocated by Clay of Birmingham; there has been developed since then the molasses treatment; soap solution and ox-gall; cancroin, a poisonous product of cancer-tissue; thyroid extract; trypsin and amylopsin as strongly recommended by Beard; atoxyl by Skene Keith; Reicher's injection of epinephrin into the tissues about carcinomatous growth; Spiess' "337," an anesthetic not on the market, similar in chemical structure to novocain, by which Spiess obtained brilliant results in the carcinomas of mice, and Uhlenhuth's injection of pyocyanase. And now, among the most promising, at least from the laboratory point of view, are the selenium and tellurium compounds of eosin introduced by Wassermann and based on the fundamental work of Ehrlich. With these can also be considered the use of the colloids of certain metals, especially silver, copper and gold, as described by Caspari, Neuberg and Loeb. Under this general subdivision may also be placed serotherapy, namely, the fetal autolysates of Fischera and emulsions of Levin and Babcock; organ extracts treated by the Roentgen ray and autoserotherapy as described by Hodenpyl and Ill. These methods have excited great interest from the point of view of the experimental laboratory. This has been especially true of the fetal autolysates of Fischera, which, from the scientific point of view at least, have much to commend them.

Among the rest may be mentioned the serum of animals treated with cancer by Jensen; autolysated sarcoma by Blumenthal; epinephrin and antivenin horse-serum of Greenbaum, and defibrinated blood by H. C. Ross and Bier. I purposely omit a bibliography as not being germane to the subject-matter, and would refer the reader to the status of carcinoma therapy as given in the *Reports of the American Association for the Study of Cancer*, 1913.

In spite of our wishes and hopes, all of these methods have proved to be inconstant in their effects, and therefore unreliable and disappointing. From the general agents used in attempts to destroy carcinoma, such as these just mentioned, we can pass to those employed locally. Among the first is probably arsenic, and its history is neither unimportant nor disappointing, although it has been badly used in many instances. With the arsenic, zinc chlorid, calcium carbid and acetone have also been employed.

The Roentgen ray has played an important part in the local treatment of cancer, and it is probable that it is destined to play a greater rôle if the work of Baum of Berlin and that of Kroenig and Gauss of Freiburg holds up its early promise. That the Roentgen ray will inhibit and destroy the carcinoma cell, or germ, under favorable conditions, there can be no reasonable doubt. There remains for the physicist only the problem of making the rays reach in an effective way the most inaccessible regions of the body, the habitat of cancer.[1]

Radium also comes in this category. In reference to this agent, all that can be said at present is to express the hope that at least half the enthusiasm shown by the few who have had the rare opportunity of using it in large quantities will prove to be justified by subsequent results. Various modifications of the electric current also deserve recognition in the local treatment of cancer. With these, as with the Roentgen ray, the problem is also one of sufficient penetration to destroy the pathologic tissue, and leave, with the least amount of damage, the uninvolved tissue-cells. There are many of these methods. The most attractive, and, perhaps, the most promising, is the so-called fulguration method of de Keating-Hart, and also his thermoradiotherapy method. The diathermy system of Nagelschmidt and the electrocoagulation developed by Doyen of France belong to this same type. That these are scientific and based on good theoretical, as well as experimental data, there can be no question.

Finally, we have, as a last hope in the management of inoperable carcinoma, the operative treatment so well set forth by Mr. Cecil Rowntree.[2] The essence of this author's paper is the relief of suffering by the excision of the growth as far as possible, without too greatly endangering the life of the patient. Added to this is the expectation that death by metastasis will be more merciful than ulceration and septic absorption.

---

* Read before the Western Surgical Association, Dec. 19-20, 1913.

[1] Recently my attention has been called to a new and powerful Roentgen-ray tube devised by W. D. Coolidge, and described in the American Journal of Roentgenology, January, 1914, p. 115. In the same journal, p. 125, Dr. Lewis Gregory Cole gives "A Preliminary Report on the Diagnostic and Therapeutic Application of the Coolidge Tube." He closes his report with the following: "With these forces under control, there is no limitation to the amount of ray at our command, and with the cross-fire method of application and the screen materially increased, there is every reason to hope that we may be able to apply to internal cancers the same amount of x-ray which, when applied to superficial cancers, has caused their immediate disappearance." This statement of Professor Cole leads one to believe that the physicist had already made it possible for "the rays to reach in an effective way the most inaccessible regions of the body."

[2] Rowntree, Cecil: Brit. Med. Jour., Sept. 27, 1913.

As already stated above, under the head of general methods, these various procedures, although of the highest scientific interest, are too indirect for consideration in a practical way at this time. In an effort to determine an agent, aside from surgical means, to eradicate carcinoma, numerous observations have been made on the vulnerability of cancer-cells to various physical and chemical agents. In 1905, Haaland,[3] in attempting to obtain artificial purification of mixed tumors, following the suggestion of P. Ehrlich, showed the susceptibility of inoculable material to heat of 44 C. (111.2 F.) for half an hour. Ehrlich suggests that with higher temperatures, fewer and fewer cells survive. Haaland likewise showed that carcinoma-cells succumb before sarcoma. Clowes[4] demonstrated the death of all tumor-cells exposed to a temperature of 45 C. (113 F.) *in vitro*, and called attention to the fact that weak strains of tumors increase in virulence when incubated at from 38.5 to 41 C. (from 101.3 to 105.8 F.), while the opposite is true of strong strains.

Jensen[5] has placed the vulnerability of cancer cells at 47 C. (116.6 F.) for five minutes; Loeb for sarcoma 45 C. for thirty minutes; Clowes and Baeslack 44 C. for thirty minutes.

Lambert[6] has recently pointed out that temperatures above 42 C. (107.6 F.) were distinctly harmful, and that the degree of injury to both normal and cancer-tissue depends on the degree of temperature and length of exposure. He further states that sarcoma-cells are destroyed by exposure to 42.5 C. (108.5 F.) for from twenty-four to forty-eight hours, 43 C. (109.4 F.) for six hours, 44 C. (111.2 F.) for fifty minutes and 46 C. (114.8 F.) for twenty minutes; while normal connective-tissue cells survive these various exposures.

M. Doyen, in proposing the *Micrococcus neoformans* as the cause of carcinoma, showed that the death-point of cancer-cells is from 55 to 56 C. (131 to 132.8 F.), identical with that of the *Micrococcus neoformans.*

E. Vidal[7] noted the arrested evolution of tumors in four patients with a temperature above 40 C. (104 F.). In order to be sure that there was not a quadruple coincidence, he daily exposed tumor-bearing mice to temperatures above normal, and found that they lived longer and that the tumors were the seat of degenerative changes. In a bitch having a spontaneous lymphosarcoma, the zone of Richet was punctured, the temperature rose to 40.8 C. (105.3 F.) and the tumor diminished in size rapidly and finally disappeared some time after this procedure. In this connection Vidal makes the startling and original observation that the methods of treating carcinoma by vaccines and toxins, such as the nectrianin of Bra, Doyen's *Micrococcus neoformans* vaccine, toxins of Coley, vaccine of Otto Schmidt, etc., are all attended by a reaction, the principal symptom of which is an increase of temperature, and when such reaction is absent, the several authors state that there is no salutary influence on the carcinoma. He therefore concludes that these various methods owe their success largely to their fever-producing qualities. It may here be mentioned that Bier[8] has shown that the injection of a foreign defibrinated blood is attended by fever, and it is well known that the intravenous injections of colloidal metals show the same reaction. The various reports of diminution of malignant tumors following infections, such as erysipelas, assume a new significance.

Based on the foregoing experimental data, it is logical that we hope for the eradication of cancerous growths by attacking these morbid processes through their vulnerability to heat. It is immediately apparent that methods tending to raise the general temperature of the body above 104 F. (40 C.) are at times dangerous, always uncertain and beyond the power of regulation. It, therefore, remains to develop a method of applying heat to the tumor mass to a degree of efficiency that will permit of the greatest destruction of carcinoma-cells with a maximum conservation of normal tissue-cells. The methods which may be enumerated to obtain these results are hot air, hot water, electrocoagulation, fulguration and actual cautery. The first two may be readily dismissed, because the penetration of hot water, as shown by Doyen,[9] is from but 4 to 5 mm., and that of hot air is probably much less. Electrocoagulation will produce a coagulation of tissues from 5 to 8 cm. in two minutes, when the electrode is in immediate contact with the tissues. The rapidity of this action, the inability to direct and control the electrode within the cavities, aside from the costly and complicated apparatus required, together with the refinement of technic and specialized judgment of the operator, make this method impracticable in the treatment of the cavity carcinoma.

In considering the de Keating-Hart method of fulguration, a method applicable to superficial growths after their surgical removal, it is not amiss to call attention to the work of Durig and Grau,[10] who show that the effects of the application of high-frequency currents is due to heat alone, and not to any specific action on the tissue-cells. In comparison with the difficulties of the application of the foregoing methods, I have devised a practical method for the application of heat in the treatment of carcinoma that has none of the objections that the various methods already enumerated have. The penetration of the heat by the method to be outlined can be definitely determined and regulated. Its applicability has almost no limitations, when the malignant process is at all accessible; the required apparatus is not expensive, and it is easily portable. The method to which I refer is the application of heat from an electrocautery, accurately controlled by a rheostat, and applied to the affected tissues.

In an effort to determine the degree of heat resulting from the application of the heating-irons for varying periods of time, the following experiments were performed:

[9] Doyen: Quoted by Bainbridge, William Seaman: International Clinics, 1913, iii, 280, S. 23.

[10] Durig, A., and Grau, A.: Der Energieumsatz bei der Diathermie, Biochem. Ztschr., 1913, xlviii, 480. Quoted in The Effects of High-Frequency Currents, editorial, The Journal A. M. A., May 31, 1913, p. 1907.

Experiment 1.—Into a mass of fresh, tightly bound beef 7 inches in diameter and 6 inches thick, the largest electric cautery was allowed to burn its way under pressure. Two thermometers were forced into the mass at 1 and 2 inches' distance from the cautery, respectively, and the cautery was allowed to act continuously at constant heat for seventy-five minutes. Cross-section of the mass following the experiment showed just outside the area of actually destroyed tissue (charcoal) an area of coagulated tissue ¾ inch thick, and to the outer side of this, an intermediate pale grayish-pink zone ½ inch thick. In every instance the latter area was found to be to the inner side of the thermometer, which registered 55 C. (131 F.).

Experiment 2.—A similar cautery was forced into a mass of tightly bound beef-muscle measuring 3½ by 3½ by 3 inches, and allowed to act continuously at constant heat for sixty minutes, and with a thermometer placed in the mass at a distance of 1½ inches from the cautery. Cross-section of the mass then showed a coagulated zone ⅜ inch thick, and an intermediate zone ¼ inch thick. Thus there is seen the actual destruction of a mass of tissue measuring 2⅜ by 2⅜ by 3 inches.

In both of these experiments, frequent thermometer readings showed an almost constant rise of 0.5 degree C. per minute in the tissue within from 1 to 2 inches of the cautery.

Experiment 3.—The cautery, heated to a bright cherry red, was allowed to act for ten minutes within a mass of tightly bound beef-muscle. At the end of this time, cross-section showed a coagulated zone ¼ inch wide, and an intermediate zone ⅛ inch wide. This experiment illustrates most graphically the inhibition by the charcoal core of the dissemination of heat. High degrees of heat in the cautery head thus defeat the purpose of this technic, through the formation of an almost impenetrable carbon barrier. It is well to emphasize here the importance of Experiment 5, in which the tissues were not carbonized by high degrees of heat, with a resulting coagulation of the tissues throughout a far greater area.

Experiment 4.—This was the same as Experiment 3, with the cautery acting for thirty minutes. Cross-section then showed a coagulated zone of ¼ inch, and an intermediate zone of ¼ inch.

In all of the foregoing investigations, it is to be emphasized that the cautery was inserted hot, and allowed to act under high heat.

Experiment 5.—From the center of a mass of tightly bound beef-muscle 2½ inches in diameter and 3 inches thick, a core ½ inch in diameter was bored out. Into this the cold cautery was inserted and allowed to remain at a heat too low to cause charring of the tissue, for sixty minutes. At the end of this time, the entire mass was hot, and cross-section showed complete coagulation throughout the mass.

Experiment 6.—In this experiment, a mass of beef 3 by 3 by 4 inches was used, the object being to determine the time necessary entirely to destroy this mass by the cautery heat, combined with external pressure by forcing the tissue on the cautery, in this way stimulating the actual operation in my technic of applying heat to a carcinomatous uterus. The mass was held in the hands of an assistant, who exerted constant pressure toward the cautery acting at high heat within the mass. At the end of twenty-eight minutes, the entire lump was too hot to be held in the hands, and section showed nothing left but a charcoal shell surrounded by a rim of well-cooked coagulated tissue ⅜ inch in thickness.

Experiment 7.—From a large mass of beef-muscle, a core ¾ inch in diameter was bored and lined with a rubber glove. The opening of this cavity was then closed by a cork containing an inlet and a smaller outlet. To the inlet was connected an irrigator containing cold water, which was allowed to flow through the cavity in the meat. The heated cautery was then plunged into the mass at a distance of ½ inch from the cavity in which the cold water was flowing, and allowed to act for thirty minutes.

The object of this investigation was to determine the effect of cold water within a cavity in protecting directly contiguous tissue from coagulation by the heat from the cautery. Cross-section of the mass showed complete coagulation of all the tissue between the cautery and the cork inserted into the cavity, but a zone of unharmed tissue ⅛ inch wide along the edge of the water-cooled cavity.

From the foregoing experiments several important facts may be deduced. The temperature within the mass of tissue, measured at a distance of from 1 to 2 inches from the outside of the heating-iron, rose 0.5 degree C. per minute, the rheostat reading high. This fact affords a method for the relative measurement of heat during the cautery operation. The time of exposure and reading of the rheostat being the factors considered in the calculation. It will be seen that a considerable area of tissue, far beyond the zone of coagulation, was heated to a degree sufficient to kill carcinoma-cells.

The penetration of heat into a mass is dependent on the following factors: (1) the density of the mass; (2) the compression of the mass on the cautery; (3) the degree of heat developed and length of exposure, and (4) the type of entrance made for the cautery.

Experiment 5 shows in a startling manner that if a charcoal core is avoided, the area of coagulation far exceeds in size that ensuing from the application of greater heat for a longer period of time. In this experiment the cross-section shows that without carbonization, coagulation is produced 2½ inches in all directions from the surface of the heating-iron, the heat being applied for sixty minutes. When the iron was heated to a degree at which carbonization was produced, as in Experiment 2, again for sixty minutes, coagulation was produced for only ⅜ inch, and an intermediate zone of ¼ inch, making a total penetration of the heat into the beef mass of only ⅝ inch, in contrast to Experiment 5, with a much lower degree of heat, of 2½ inches from each side of the heating surface.

This emphasizes the caution which I have advanced on former occasions, not to produce too great a heat in the heating-iron; it is far better to develop a heat below the degree of carbonization, and allow it to act for a long time. As can readily be seen from these experiments, there are two methods by which a carcinomatous mass may be destroyed: first, that illustrated in Experiment 6, in which, with the heating-iron at high temperature, the mass is burned up, every angle being pressed on the cautery head by an assistant, and second, that illustrated by Experiment 5, in which the tissue is not burned up, but destroyed by the production of heat below the point of carbonization. Both procedures have a place in the operation. When a small, circumscribed and well-defined growth, unattended by pelvic metastasis, is present, the first method may well be used, particularly as a preliminary measure. When, however, the pelvis is filled with the cancer growth, the first method should not be employed, because the primary carbonization, I repeat, prevents in a remarkable way the dissemination of heat necessary to effective treatment of the cancer mass. In other words, the successful treatment of cancer depends more and more on the question of heat, and less and less on the effects of cauterization. There is another important consideration, which should guide us in reference to the prevention of the formation of the charcoal core at the point of contact with the cautery, namely, drainage. The charcoal not only prevents the scattering of the heat, but also interferes with subsequent drainage, which is a most important factor in the successful management of these cases. When the drainage is not adequate, the patient is in danger from absorption of the products of large quantities of killed cancer-cells. Wassermann has already called attention to this in the destroyed tumors of mice. He has shown that if the destroyed tumor in these animals was as large as, or larger than, a hazelnut, the animal died from intoxication from the lytic cancer-cells. If, however, the tumor was the size of a large pea, this result did not follow when it was destroyed. In two of my cases, I have observed intoxication of this character. In both of these cases the pelvis was full of secondary carcinoma following panhysterectomies. The heat was applied through the vagina, and in both instances there was a perfect primary recovery. After four days, however, each of these patients showed signs of failure, which was expressed by extreme weakness, which could not be explained by any local findings. There was also a rapid and weak heart-action, associated with syncopal attacks, vomiting, marked stupor and finally an acidosis. The second method is much more effective, carried out for a period of time varying with the size of the mass; the heat radiates from the heating-iron in a circumferential manner and penetrates the tissues as outlined in the foregoing experiments.

The scope of this paper and the tenor of its contents does not permit of a description of the various steps of my operation, the indications, contra-indications and the immediate, together with the final results. Permit me to refer to my two previous articles on this subject for this data.[11]

CONCLUSION

It has been my purpose to try to point out, through the medium of this paper, the widening of the field of investigation regarding the vulnerability of the cancer-cell to the effects of heat. It will be of particular interest to make further observations as to the relation of the reaction, producing heat in the body, following the injection of toxins, serums and vaccines in the destruction of carcinoma. If the primary gross mass of cancer which is usually accessible can be rendered innocuous by raising the temperature through the medium of an electic heating-iron, and the remaining small amount of lymphatic involvement be reached by thermic-raising, artificially produced toxins, serums or vaccines, as is emphasized by Vidal, then the dream of the ages, on the part of the physician, of doing something with cancer, will be on the road of realization.

Finally, it becomes necessary to develop the application of heat by a method which is at once efficient and harmless, and I believe that I have done this by the technic which I have developed. I believe, further, that I have accomplished this in such a way as to make it highly probable that many forms of carcinomatous growths may be eradicated.

DEEP WOUND OF BRAIN

F. H. Gunn, M.D., and H. C. Fairbrother, M.D.
East St. Louis, Ill.

Patient after recovery from deep wound of brain.

G. R., a Greek, aged 35, blacksmith, of robust physique, while engaged in a fight with another Greek, Dec. 27, 1913, received a stroke with an ordinary chopping-ax. As shown in the accompanying illustration, the head was literally split wide open. The skull was severed back to the coronal suture, and forward through the malar and superior maxillary bones down to the alveolar arch. The brain was severed about 1 inch to the left of the median line, through the frontal lobe back to a point near the fissure of Rolando. The left eye was cut through near the center. The patient was brought into the hospital, the head shaved and cleaned, the eye removed, the incision closed and secured with sutures and adhesives, and absolute rest enjoined. Perfect recovery followed without an untoward symptom. In five weeks the patient returned to work, and up to the present time, a period of three months, he has complained of no unfavorable symptom except occasional insomnia.

The Increase in the Number of the Insane.—Interesting statistics have been recently published by Dr. Magnan, head of the examination service of St. Anne's asylum, and by Dr. A. Fillassier, head of the statistics department of Paris, on the insane of the Department of the Seine.

During the period between 1871 and 1880, inclusive, the total number of cases of insanity in the Department of the Seine was 27,169. From 1881 to 1890, the cases furnished by the department numbered 41,288. During the third decennial period, from 1891 to 1900, the number of insane rose to 42,138. Finally, between 1901 and 1910, 43,035 cases of insanity were registered. Alcoholics formed more than a fourth of the number of insane. Of the 89,728 total admissions between 1887 and 1911 the number of alcoholics was 27,315.

The number of relapses, according to Magnan and Fillassier, is very high: in 1911, 15.3 per cent. for the men, and 11.3 per cent. for the women. Many of the relapses are due to alcoholism. Sometimes the cases are merely those of alcoholics who return to drinking, sometimes of degenerates who, from the effect of the poison, become insane anew. Among the exceptional relapses were those of some patients who entered St. Anne's fifteen, sixteen and seventeen and even forty times because of the abuse of intoxicants.

Of all the methods applied for the treatment of the various cases of insanity, Drs. Magnan and Fillassier believe that confinement to bed is the one which gives the best results. This method constitutes a considerable step in advance in the therapeutics of mental diseases. By confinement in bed the acute deliriums are improved, arrested and cured. Since 1897 a considerable diminution of suicides has been observed among men, and there have been none in the women's division. The amelioration of the maniac and melancholic condition is constant and often rapid. For the alcoholic, nothing can equal the value of confinement to bed.

New Instruments and Suggestions

ACROMION AUSCULTATION: A NEW AND DELICATE TEST IN THE EARLY DIAGNOSIS OF INCIPIENT PULMONARY TUBERCULOSIS

Frank A. Bryant, M.D., New York

The early recognition of physical signs in incipient pulmonary tuberculosis is a factor of such importance that the discussion of a new method of detecting conditions which produce slight pneumatic changes in lung-tissue should prove interesting.

The primary lesion in tuberculosis of the lungs is, as a rule, in one of the upper lobes (American System of Practical Medicine). In 427 successive cases of pneumonic tuberculosis examined at the Johns Hopkins Hospital, the right apex was involved in 172, the left in 130, and both in 111. This leaves only 14 cases out of 427 in which the initial lesion was elsewhere than at the apices.

It may be stated that phthisis in this locality is practically always caused by the aspirated tubercle. In this method of infection the tuberculous nodule is usually deposited just where the bronchiole loses its cartilaginous quality, becomes membranous and narrows down to enter the aveoli. Almost immediately (Osler, in Loomis-Thompson's Practice of Medicine) cell proliferation and tissue changes begin so that as early as the fifth day after infection, variations in the lumina of the air passages are sufficient to cause changes in the pitch of the respiratory note and prolonged expiration.

This early mechanical change in the walls of the smaller air-passages explains how by means of auscultation alone the very earliest evidences of infection and infiltration may be obtained, long before such a condition could be detected by percussion, cough, pallor, nocturnal perspiration and the more common signs by which lung tuberculosis is ordinarily diagnosed.

A new and delicate method of auscultation to which I desire to call additional attention and which has been described by Robert Abrahams and Nathan Magida, is called acromion auscultation (Abrahams, Robert: Auscultation at the Acromion Process: Its Significance in Apical Disease, *Arch. Diagnosis,* April, 1913. Magida, Nathan: Acromial Breathing as an Aid in the Diagnosis of Apical Pulmonary Tuberculosis, *New York Med. Jour.,* 1913, xcviii, 1261). It is, as its name implies, a process of listening with a bell-stethoscope (or stethophone, as some prefer to call this instrument) over the acromion processes of the scapulae and particularly over the clavicular-acromion arthroses. It is of such significant service in ascertaining the very earliest signs of the invasion of pulmonary tuberculosis, that I believe it should be given a high place among the classical and recognized signs of this disease, and command the attention and respect which its useful character deserves.

ACOUSTIC PRINCIPLES

Acromion auscultation is based on the principles involved in the production and transmission of sound. It is a fundamental law of physics (Avery, E. M.: Elements of Natural Philosophy) that all sound may be traced to the vibration of some material substance. The sounds heard by direct auscultation over lung-tissue are produced by vibrations or movements of air, and occasionally mucus, within its substance. As a medium for the transmission of these vibrations in acromion auscultation, we have, first, the clavicles. It is worthy of note that the name is derived from the Latin word for key, inasmuch as they help to unlock some problems in the physical examination of the upper chest.

The clavicles, on account of the connection at their inner ends with the manubrium and first ribs, whose posterior surfaces lie directly over lung-tissue, and with their own inner concave surfaces lying across and on the apices of the lungs, act like the sounding-board of a musical instrument whose office is to greatly increase the intensity of the original vibrations.

Sound waves produced in the lungs are thus picked up, and traveling longitudinally through the long axes of these bones, are, according to a principle in acoustics, reenforced by the blending of similar waves and sympathetic vibrations. As in the case of the violin, the result is an intensification and even increase in volume of sound at their acromion ends.

This multiplication of sound at the acromion is analogous to the fact that a tuning fork can be heard much louder if it be placed against the end of a rod whose opposite end is held against the ear. Another familiar illustration of such bone conductivity is the increased resonance heard as the razor in shaving glides over the rami of the inferior maxillary. The telephone is another extensive example of the same principle.

The same conditions and principles which apply to the clavicles anteriorly obtain in the relation that the large resonant surfaces of the upper portion of the scapulae bear to the lung-tissue which they cover and to the acromion processes. It is apparent, therefore, according to physical laws, what effective collectors, intensifiers and transmitters of adventitious apical sounds these two bones may become.

METHOD OF USE

The manner of its use is exceedingly simple. The bell of an ordinary stethoscope should be placed as nearly over a point corresponding to the junction of the clavicle with the acromion process as possible. The effect of ordinary respiration should first be observed, after which the patient should be told to deepen the natural breathing, to count, to whisper or to cough, according to whichever sign it is sought to make available, as in the direct auscultation of the apices.

If the anterior portion of an upper lobe be suspected, the examiner should then stand at the side of the patient and endeavor to cover with the stethoscope a portion of the outer or external end of the clavicle by applying the bell of the instrument as nearly as possible in conformity with its long axis.

This manner of applying the stethoscope is recommended because the inner end of the clavicle, articulating as it does with the manubrium and first rib, and being bound firmly to the rib by the aponeurosis of the subclavius muscle and the costoclavicular ligaments, forms a fairly broad, compact resonating surface in direct contact with the anterior portion of the upper lobe and its apex. This resonant mass of bone and fibrous tissue acts as a collector of sound-waves, which it transmits longitudinally outward along the clavicle to its acromial end.

If the posterior portion of the upper lobe or its apex is to be tested, the examiner should stand in front of the subject and place his instrument on and as nearly over the tip of the acromion process as he can. In this locality the supraspinous fossa above and the under surface of the great shell-like subscapular fossa below spreading out over this region, lying on the posterior surfaces of the upper ribs, which in turn through their pleurae come into contact with lung-tissue beneath, act as other resonators, gathering up, intensifying and transmitting sound impulses to the listener's ear at the acromion.

While the chief use of acromion auscultation is to be found in its use in the incipient stage before emaciation has taken place, yet it is desirable occasionally to use it in later stages of the disease and when there has been a loss of flesh. This often leaves the bony prominences of the shoulder so uneven that the bell of the stethoscope cannot be adjusted readily to the contour of the shoulder in a manner to exclude the external air.

At first a soft rubber bell was used on the stethoscope, but that absorbed the sounds to such an extent that its use had to be abandoned. Later I found that the ordinary hard rubber or metal bell could be used on these bony shoulders by simply drawing up the loose skin and tissues around the mouth of the stethoscope with the fingers of the disengaged hand sufficiently to make an air-tight adjustment. Care must be taken, however, to keep this skin cushion motionless, or else extraneous and confusing sounds will be heard.

Rarely, slight friction sounds produced by a movement of the parts in the clavicular-acromion arthrosis may be heard, and on account of their similarity to those of mucus râles and clicks, caution must be used to differentiate and exclude such sounds from those originating in the lungs. I would suggest that cases for examination at first be chosen from those which have already been diagnosed by other means as being tuberculous. For those unaccustomed to this method of examination, like the early study of heart murmurs, it will give greater satisfaction and confidence to begin the investigation with a known condition as a working hypothesis.

The bell stethoscope must always be used, because the phonendoscope, on account of its flat surface, cannot be adjusted to the rounded and sometimes bony prominences of the shoulder-joint.

ADVANTAGES

The primary and most valuable feature of this new method of auscultation is in its being an early indicator of apical invasion. Its basic principles are well adapted to collecting and transmitting to the ear pathognomonic sounds about the apices due to changes in the walls of the infundibula earlier in the history of the disease than they can be elicited in any other way.

In addition to this it is useful in determining the stage of the disease. In a stated number of cases of all stages of lung tuberculosis examined, acromion breathing was heard in all of the first-stage cases, in 57 per cent. of those in the second stage, and in only 2 per cent. of the third-stage cases. I have found it useful also in young, plethoric persons, in whom the presence of pathogenic bacilli is apt to be made known first by hemoptysis. In this class of cases there is frequently so much fatty tissue and muscle over the apices that little or nothing can be learned by direct auscultation or percussion. In such cases the value of acromion auscultation is emphasized.

62 West Fortieth Street.

MARCHI TECHNIC: SAFER AND EASIER CLEARING AND MOUNTING OF CELLOIDIN SECTIONS*

H. S. Steensland, M.D., Syracuse, N.Y.

This communication is presented on the assumption that, at present, chloroform is generally regarded as the best clearing reagent for Marchi celloidin sections. It is generally recommended that Marchi celloidin sections be cleared in chloroform and mounted in chloroform balsam because xylol and other clearing reagents, and xylol balsam, cause the black osmic acid staining of fat to fade. Clearing in chloroform, as recommended, presents certain well-known difficulties in technic. These difficulties sometimes make the fate of valuable material uncertain, for example, material that has been obtained as a result of painstaking and time-consuming experiment.

Obviously it would be a great advantage if such sections could be cleared in oleum origani cretici. The technical difficulties dependent on chloroform clearing would be overcome. There would be no danger of drying and shriveling of the sections. The sections could be thoroughly blotted and flattened with smooth (not embossed) filter-paper. The chloroform balsam could be carefully applied. The retraction of the balsam, on drying, from a part of the space between the cover-slips and the slides would be practically done away with. Dr. Mallory has informed me that this retraction can be still further guarded against by completely covering the sections on the slides with chloroform balsam and then allowing it to evaporate to a proper thickness before putting on the cover-slips. It would be possible to turn over valuable material to a technician for clearing and mounting with much less fear of loss of material and without placing undue responsibility and strain on the technician, especially in the case of large serial sections.

Marchi celloidin sections were placed in a dish of oleum origani cretici. Sections of Zenker-fixed tissue stained in hematoxylin and eosin were placed in another dish of the same oil. Oleum origani cretici is probably the most widely used clearing reagent for hematoxylin- and eosin-stained sections. At intervals, sections from each dish were mounted, the Marchi sections in chloroform balsam and the hematoxylin and eosin sections in xylol balsam. In the Marchi sections no evidence of fading was found after seven weeks in the oil. On the other hand, the hematoxylin and eosin sections had obviously faded.

Further, a large number of Marchi celloidin sections were mounted. The technic made use of was the usual technic except that the sections were cleared in oleum origani cretici instead of chloroform. At the end of ten years these show no evidence of fading on comparison with controls. The controls consist of new sections cut from the same set of blocks from which the oil-cleared sections were cut ten years ago. These control sections were cleared in chloroform.

Dr. Mallory has kindly examined the various sections mentioned above and has confirmed the observations.

CONCLUSION

Oleum origani cretici is a very much safer and easier clearing reagent than chloroform for celloidin sections to use in the Marchi technic. It is a safer clearing reagent for Marchi sections than it is for hematoxylin and eosin sections.

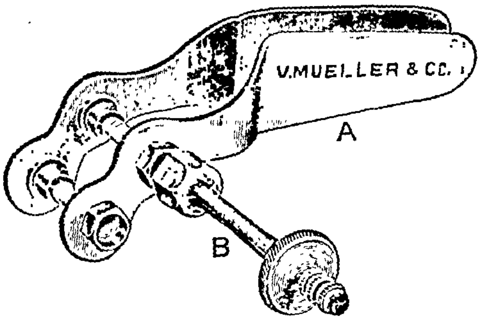
A NASAL SPLINT

E. P. Hall, M.D., Kansas City, Mo.

The suffering of the patient whose nasal chambers are tightly packed with gauze for the twenty-four to forty-eight hours following the submucous resection of the septum must be a consideration which presents itself to the mind of the rhinologist when advising this otherwise excellent procedure. The obstruction to drainage of the nasal secretions except by seepage through thoroughly saturated sponges; the absence of oxygen with its bacteria-inhibiting power and consequent protection against increased virulence of existing sinusitis, and the possibility of direct infection of the wound are conditions all against surgical principles, and condemn this method.

A satisfactory nasal splint would be one to hold the flaps securely in position, to prevent hemorrhage, to offer no obstruction to discharge of nasal secretions and to permit free nasal respiration. The instrument here illustrated, when applied in the manner described, I have found to meet these requirements.

When the operation is completed, a strip of Bernay's sponge three or four layers in thickness, cut to size of blades or a trifle wider, is placed on both sides of the septum and the blades of instrument are guided into position over these strips. The blades of the splint are not screwed tightly against the flaps, for the intervening packing affords the necessary elasticity to the splint to provide for the edema of tissue and to fix it immovably in position.



Nasal splint.

An adhesive-plaster strap is wound once around connecting bars and carried along the bridge of the nose to the forehead; this, with a cross-strap over the bridge, supports the weight of the extra nasal end of the splint. The screw-heads are grooved for insertion of a key to assist in turning the cogs to separate the blades when secretions and blood have cemented the working parts together.

Triangular plates held to grooves in the blades of the splint can be placed in position, taking care of a high operation should it be found necessary to support the entire flap.

The instrument may be so constructed that the blades are placed in position separately and then locked together. This is a later development of the device and preferable in that it is much easier to insert and remove without discomfort to the patient.

My experience justifies a recommendation of at least forty-eight hours for the length of time to leave the splint in position.

Models of this instrument are in the hands of V. Mueller & Co., Chicago.

New and Nonofficial Remedies

The following additional articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council. • Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies."

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that, so far as known, it complies with the rules adopted by the Council.

W. A. Puckner, Secretary.

THIOCOL AND SYRUP THIOCOL, ROCHE

Report of the Council on Pharmacy and Chemistry

The following report, explaining the readmission of Thiocol and Syrup Thiocol, Roche, to New and Nonofficial Remedies, was adopted by the Council and authorized for publication.

W. A. Puckner, Secretary.

Seven years ago the Council accepted Thiocol for inclusion with New and Nonofficial Remedies (The Journal, Dec. 22, 1906, p. 2093) and later also a preparation of it, Syrup Thiocol, Roche (The Journal, Dec. 3, 1910, p. 1980.) About a year ago the Council learned that a preparation called Sirolin, containing Thiocol as its effective component, and practically the same as Syrup Thiocol, Roche, was being advertised to the public both in this country and abroad under grossly exaggerated claims. The Council directed that the matter be brought to the attention of the American agent for Thiocol preparations, the Hoffmann-LaRoche Chemical Works. This was done.

The agent's reply contained no promise that advertising in the lay press would be discontinued. As the Council holds that the advertising of medicinal products to the public is vicious in that it tends to encourage self-medication and the establishment of false security on the part of the public, the Council voted that Thiocol and Syrup Thiocol, Roche, be omitted from New and Nonofficial Remedies (The Journal, June 21, 1913, p. 1974).

Recently the following was received from the Hoffmann-LaRoche Chemical Works, New York:

> "All popular propaganda for Sirolin has been abandoned in Germany, Russia, Great Britain and the United States and there never has been any popular propaganda of Sirolin in France. We can at the same time state that there will not in future be any popular advertising or popular propaganda of any sort in behalf of Sirolin in the United States, Germany, Russia, Great Britain or France."

In view of the foregoing letter the Council has voted that Thiocol and Syrup Thiocol, Roche, be readmitted to New and Nonofficial Remedies.

NEW-BORNYVAL.—Neo-Bornyval.—New bornyval is borneol isovaleryl glycolate, $(CH_3)_2:CH.CH_2COO.CH_2.COO.C_{10}H_{17}$, the isovaleryl glycolic acid ester of borneol.

Actions and Uses.—New bornyval is more resisting to the gastric juice than bornyval, and is said to pass the stomach without decomposition and on this account it is said to be less irritating to the stomach than bornyval. In the intestine it is decomposed into borneol, and the salts of valeric acid and glycolic acid.

The actions and uses of new bornyval are similar to those of bornyval or to preparations of valerian. It is said to be useful in the various neuroses, especially those of the circulatory, digestive and central nervous systems.

Dosage.—From 0.25 to 0.75 Gm. (4 to 12 minims) from two to four times daily. It is best given after meals with some milk, coffee or similar drink to avoid eructations.

Manufactured by J. D. Riedel, Aktien Gesellschaft, Berlin, Germany (Riedel and Co., New York). No U. S. patent. U. S. trademarks Nos. 41,917 and 56,450.

New Bornyval Pearls.—Each capsule contains new bornyval, 4 minims.

New bornyval is prepared by heating equivalent amounts of borneol chloracetate with salts of valerianic acid and subsequent purification by distillation *in vacuo*.

New bornyval is a colorless, nearly tasteless and odorless, oily liquid, insoluble in water, readily soluble in alcohol, ether, benzene and fatty oils. The alcoholic solution is neutral to litmus. It has a specific gravity of from 1.025 to 1.030 and boils at 181 C. at 12 mm. pressure, and from 283 C. to 285 C., with decomposition, at 760 mm. pressure.

If about 6 Gm. new bornyval be saponified by boiling for one hour with from 50 to 100 Gm. of an alcoholic solution of potassium hydroxid (10 per cent.) under a reflux condenser, the alcohol distilled off, and the remainder distilled with steam, crystals will be formed in the condenser which, after recrystallization from petroleum ether, may be identified as borneol by their appearance, odor and melting-point. If the liquid from which the borneol was distilled be made acid and heated, the odor of isovalerianic acid will be apparent.

Therapeutics

SOME OVERLOOKED CAUSES OF CHRONIC ILLNESS

Misdirected treatment is unfortunate, for both the patient and the physician; the former loses time and comfort, if not health, and the latter loses the patient. Consequently, a brief reference to some of the conditions in which the etiologic factors are sometimes overlooked, and therefore the treatment wrongly directed may not be amiss.

LINGUAL TONSIL COUGH

A congested lingual tonsil as the cause of a troublesome, dry cough is frequently overlooked. This is a common condition, and may occur without bronchitis, tracheitis or laryngitis. It may also occur without a pharyngitis, although it is frequently associated with it. It is frequent in cigarette smokers, and more or less in all smokers, but often occurs in patients who do not smoke. If a person has had this trouble once he is likely to have it recur with every cold. It not infrequently happens that a patient is suspected of having incipient tuberculosis, just because he has a lingual tonsil cough, especially if the hard, rasping cough has produced a blood-tinged mucus. Such a cough is generally worse when the patient lies down, is precipitated by any change of temperature from the house to out-of-doors, or vice versa, from a warm room to a cold room, or the reverse. It is also precipitated by laughing. If the cough begins there is a shower of coughs, until the patient has literally scraped the part irritated, much as one scratches an itching spot until it almost bleeds. The cause of this cough is quite generally referred by the patient to a tickling well down under the sternum. The patient may not always have a cough from lingual tonsil irritation, but may complain of a burning sensation which he may term "heartburn."

The diagnosis of the condition is readily made by the use of the laryngoscope, when the lingual tonsil at the base of the tongue will be found, many times, red and inflamed, sometimes heavily coated, and at other times with large papillae projecting from the mucous membrane.

Emphasis should be laid on the fact that cough mixtures will not cure this cough. It is true that some gummy, gelatinous, sweetish, thick, syrupy preparations may so coat the lingual tonsil when they are swallowed as to ease the cough for a time; but what becomes of the poor stomach from such medication? Gargling may not reach this region; only patients who have been educated to do so can gargle to wash the lingual tonsil. Gargles should always be ordered, however; they will at least soothe the rest of the throat. Efficient gargles are the liquor antisepticus alkalinus of the National Formulary, which should be diluted with an equal part of hot or warm water; or a Seiler's tablet solution, one tablet dissolved in 2 or 3 ounces of warm water; or a simple and efficient gargle may be made by adding one-fourth of a teaspoonful of bicarbonate of soda and one-fourth of a teaspoonful of salt to half a glass of warm water. Another *useful gargle is the following:*

		Gm. or c.c.	
℞	Acidi borici.................	2	ʒ ss
	Potassii chloratis...........	5	ʒ i
	Aquae menthae piperitae....	200	fl℥ vi

M. Sig: Use as a gargle every 3 or 4 hours.

At times when the throat is flabby, a tannic acid gargle is of value, such as:

		Gm. or c.c.	
℞	Acidi tannici................	3	gr. xl
	Glycerini	10	flʒ ii
	Aquae gaultheriae q.s...	ad 200	fl℥ vi

M. Sig: Use as a gargle twice a day.

Of course, sedative cough mixtures containing codein or heroin are of benefit in reducing the irritation of the nerves of the throat, and ammonium chlorid will stimulate the mucus secretion and perhaps, sooner or later, also help the condition, but as above stated, such treatment seems unnecessary and is generally unsatisfactory in this kind of a cough. It is generally much better to give no medicine at all by the stomach. If the throat is dry, small doses of sodium iodid given three times a day will increase the mucus of the pharynx and lingual tonsil region and may aid in curing this cough.

The proper and only satisfactory treatment is by local applications. This irritated glandular tissue should be swabbed daily for a few times with boroglycerid, or less frequently with a solution of iodin such as:

		Gm. or c.c.	
℞	Iodi	1	gr. xv
	Potassii iodidi...............	3	gr. xlv
	Glycerini	30	fl.℥ i

M.

The patient should understand that if he wishes to recover quickly from his cough, daily visits to his physician will accomplish more in a week than will three months of intermittent treatment.

DISTURBANCES OF THE THYROID

The most familiar condition of hypersecretion is Graves' disease, and the condition that is so readily diagnosed as serious hyposecretion, namely, cretinism and myxedema, is also well understood; but disturbances which may be caused by a small amount of hypersecretion or hyposecretion of the thyroid, are not so readily recognized.

It should not be forgotten that this gland may hypersecrete or hyposecrete in all degrees, or the gland may have some portions of its secretion increased and others diminished. In this last condition the disturbance that it causes is very hard to overcome, as inhibiting the thyroid activity on the one hand, or feeding thyroid on the other, is not likely to effect a cure. Disturbances caused by too much or too little secretion and not by a mixed condition, however, may be greatly benefited by treatment.

About 90 per cent. of all cases of thyroid disturbance occur in women; therefore it is the condition of the gland in women that we are discussing.

The disturbances caused by an increased secretion are tachycardia or attacks of simple palpitation, nervous irritability, sleeplessness, increased perspiration, hot flashes, some digestive disturbances and a tendency to menstrual flooding. Some of the signs of hyposecretion which may not be recognized are certain forms of obesity, especially that form which, when fully developed, is typical of the picture of adiposis dolorosa; drowsiness and a tendency to sleep in the daytime, and more or less mental apathy and sluggishness; dry skin and perhaps chronic eczemas; slow pulse; often an increase in blood-pressure; various digestive disturbances, and amenorrhea or scanty menstruation before it is time for such a condition to occur.

The neurotic woman who is very active socially, good company and bright in reparteé, and who may be doing much of the good work of the world, who works on nerve and finally collapses, very generally has hypersecretion of the thyroid. It is this type that may not be hysterical as we understand major hysteria with stigmata, but such patients when they have pains have them in excess of all local cause. They eat very little, even for days, perhaps get little sleep and recuperate with difficulty after they once break down, and one breakdown is likely to be followed by others. If these patients can be made apathetic without being made melancholic, they will rapidly recover. Such patients should receive, in a modified form, the same kind of treatment that we advise in more developed Graves' disease.

It has lately been shown that some of the symptoms in Graves' disease may be due to the secretion from left-over fragments of the thymus gland. On the other hand, it should be remembered that some types of mental depression and some instances of epilepsy are due to subsecretion of the thyroid.

If it is presumed, from the symptoms, that the thyroid is subsecreting, it may be activated either by iodin or by the administration of thyroid. If the symptoms are inconclusive (that is, some symptoms showing increased thyroid secretion and some are apparent undersecretion) it will often be found that the feeding of thyroid will make the patient worse, but small doses of an iodid may aid the thyroid in recovering its efficiency. Disturbances of the menopause are due to the secretions of the thyroid, ovaries and probably corpus luteum not having become correlated to the changed condition of the woman.

ORTHOSTATIC ALBUMINURIA

Not too great reliance should be placed on the fact that a morning urine is perfectly clear of albumin. It is necessary, in a doubtful condition, that we should examine specimens of urine passed at different times during the day, unless we are careful to obtain the twenty-four-hour specimen, and even then the variations of the urine passed at different times will not be discovered. Sometimes a patient who has an albumin-free morning urine will show a large percentage of albumin in the urine at noon and in the evening.

(To be continued)

STATE BOARD STATISTICS FOR 1913

THE ANNUAL PRESENTATION BY THE COUNCIL ON MEDICAL EDUCATION OF RESULTS OF STATE BOARD EXAMINATIONS

On pages 1640 to 1649 are three tables, A, B and C, giving in detail the results of the various state medical license examinations held during 1913. These statistics are complete, since full reports were obtained from all state licensing boards.

Tables A and B have been arranged so that, read from left to right, they give the results by colleges, showing the number of graduates appearing for examination in each state, whether they passed or failed, the total number examined during the year, the number who passed, the number who failed, the percentage of failures and the number of states in which graduates of each school appeared for examination. Read from above downward, they give the results by states, showing the number registered and rejected from each college, the total number examined, the total number registered, the total number rejected and the percentage of rejections. The fact that the majority of graduates take the license examination in the state in which the college is located is shown by the dark diagonal zone made by the grouping of figures, passing from the upper left to the lower right corner of each table. This shows also that the states in which low-grade medical schools are permitted to exist are themselves the recipients of the greater portion of the ill-trained output of such schools. These tables are worthy of much careful study, for many important deductions are possible. The marginal numbers will enable the reader more readily to follow the lines for any colleges in which he is interested.

Caution in Forming Conclusions

In making comparisons on the basis of these statistics, several factors should be considered carefully. The number examined is important since, if all other conditions are equal, the larger the number of graduates examined the more accurate is the finding. But other conditions are seldom equal. The number of states in which a school's graduates have been examined is important. The larger this number the more accurate will be the conclusions. Again, the character of the board making the examination and the methods employed are important factors to be considered, since some boards hold very careful examinations and include practical laboratory and clinical tests, or they may mark the papers more severely, while others, especially partisan boards, may be very lenient. In this connection it should be stated that although conditions are undergoing a steady improvement, it is still true that the character of the license examination as usually conducted, is such that graduates of colleges conducted largely by quiz-class methods may easily be successful in passing them. It is particularly important in forming conclusions based on these statistics to note for each college the states in which its graduates *are not admitted to examinations*—information set forth for the first time with these statistics, in Table D.

Graduates of All Years Examined in 1913

Table A shows the results for all candidates who took examinations in 1913 regardless of the years in which they graduated. This shows that altogether 6,435 were examined last year, as compared with 6,879 in 1912; 6,960 in 1911; 7,004 in 1910, and 7,287 in 1909. Of those examined, 18.6 per cent. failed, as compared with 20.5 per cent. in 1912; 19.9 per cent. in 1911; 18.4 per cent. in 1910, and 19.6 per cent. in 1909. During the years 1905 to 1908 the percentage of failures each year was over 20 per cent. The rather lower percentage in recent years is doubtless due to two causes: (1) wider extension of reciprocity and (2) the fact that graduates of low-grade medical colleges are now not admitted to examinations in about thirty states (see Table D). Graduates of low-grade colleges therefore who are usually responsible for high-failure percentages are found to take their examinations in the more lenient states and as a consequence, fewer failures result.

There were 99 medical colleges in the United States granting degrees in 1913, which had graduates examined, as compared with 110 in 1912, and with 153 in 1905. Foreign graduates were examined in twenty-four states, the total number being eighty-nine; and of this number forty-two, or 47.2 per cent. failed. The largest number of foreigners examined in any state was twenty in New York. Graduates of Canadian schools were examined in nineteen states, more appearing, naturally, in the border-line states. The figures for the Canadian colleges are given separately in order to show the number of candidates coming from each as well as to show the successes of their graduates at the examinations. Altogether 58 candidates from Canadian colleges were examined, of which number 17, or 29.3 per cent., failed. Of all Canadian colleges, the McGill University had the largest number examined. The highest percentages of failures were for Laval University, 63.3, Queen's University, 40 and the University of Toronto, 20.

Undergraduates Examined During 1913

Line 107 of Table A shows the number of non-graduates examined in seven states during 1913. Altogether 251 non-graduates were examined, of which number 95, or 37.8 per cent., failed, as compared with 35 per cent. in 1912, 38.5 per cent. in 1911 and 45.6 per cent. in 1910. Such candidates were examined during 1913 in Colorado, Florida, Maryland, Massachusetts, Oregon, Tennessee and Texas. Of such candidates 1 was licensed in Colorado, 15 in Oregon, 19 in Massachusetts and 121 in Tennessee. In Tennessee in the last four years 1,187 candidates were registered by examination, and of these 515, or 43.4 per cent., were non-graduates. Meanwhile, Tennessee is now the only Southern state which has the door wide open for non-graduates and is the only state in the country which registers any considerable number of such candidates.

Recent Graduates Examined During 1913

Table B gives the results for graduates of 1909 to 1913 inclusive who were examined during 1913. This table is particularly important since it deals with recent graduates and is, therefore, the fairest basis for comparison between colleges. Such comparisons are worthless, however, unless reference is also made to Table D, showing in what states candidates are reported not eligible for examination. Of all candidates examined in 1913, 5,390, or 83.8 per cent., were recent graduates, and of this number 16.5 per cent. failed, as compared with 18.6 per cent. for all candidates. The figures for several medical schools which have ceased to exist either through merger or otherwise have been included in the line for miscellaneous colleges.

Old Practitioners Examined During 1913

Table C is so arranged as to show in comparison the results of all years (first column), for recent graduates (second column), the graduates of 1908 and previous year (third column), and the graduates of 1913 (fourth column). Of the graduates of 1908 and previous years—of "old practitioners"—794 were examined, and of this number 223, or 28.1 per cent., failed as compared with 16.5 per cent. of failures for recent graduates. This high percentage of failures is probably due chiefly to the long time these candidates have been out of college and to the fact that they are required to take the same examination as recent graduates.

---

* Nine medical colleges give only the first two years of the medical course. Work taken in six of these is apparently fully accepted by all boards for advanced standing in other recognized medical colleges. Work taken in the other three is reported not so recognized in seven states unless the student entered with two years of preliminary college work.

† At the close of the present session Dartmouth Medical College will discontinue teaching the clinical branches.

‡ Third Classification revised to May 10, 1914. (1) Classification changed during present year.

(x) According to official reports the licensing boards of the states thus indicated do not grant full recognition to, or have taken action refusing to admit to their examinations graduates of, the colleges marked by this letter—x.

(a) Colorado registers without further examination only graduates of medical colleges in good standing who present licenses issued after examination granted by other state licensing boards. The law permits any one, graduate or non-graduate, to try the Board's written examination. No graduate, hereafter, will be eligible to license on indorsement of credentials unless he completed two years of collegiate work prior to beginning the study of medicine.

(b) Indiana, Iowa, Minnesota, North Dakota and Kentucky report that no graduate of any medical school may take examinations in those states unless before entering on the study of medicine he or she has completed two years of work in an approved college or university. This rule applies to all graduates hereafter in Iowa, Minnesota and North Dakota. This rule is reported to apply to all graduates of 1915 and thereafter in Indiana, and to all graduates of 1919 and thereafter in Kentucky.

(c) South Dakota reports that no medical college will be considered in good standing which accepts or graduates students who do not have the required preliminary education—two years of collegiate work. This has applied to all colleges since Aug. 1, 1911, and the ruling will affect all graduates of 1915 and thereafter.

CONTINUED FROM PAGE 1639

Undoubtedly the less favorable conditions in medical colleges at the time these physicians graduated have some bearing on this result. Justice to such candidates, who have been licensed, but who, for good reasons, desire to change their locations, is the strongest argument for interstate reciprocity in medical licensure, or for special percentage allowances at the examinations for years of practice. The total number of these candidates is diminishing each year as increased reciprocal relations are established. As a rule, the states which do not have reciprocal relations with other states (as Florida, Montana, Massachusetts, Oregon, Washington, see Table L) examined the largest number of old practitioners.

Graduates of 1913 Examined During 1913

Table C also gives the results for the graduates of 1913 who were examined during the year by state boards, and shows that 3,465, or 53.8 per cent. of all candidates examined during the year, graduated in 1913, including ten who graduated in Canada and other foreign colleges. Educational statistics show that the medical colleges of the United States graduated 3,981 students last year; therefore 87 per cent. of all graduates in 1913 took examinations for license during that year. In some of the states, graduates in medicine are allowed to serve hospital internships without first becoming licensed practitioners, which doubtless accounts for some of the remaining 13 per cent. Of those examined, 353, or 10.2 per cent., failed.

This table gives data relating to the group of colleges in each state. For example, it shows that, of all the medical schools in New York, 651 graduates of various years were examined by state boards during 1913, and of this number 19.9 per cent. failed. Of the 608 who graduated in recent years, however (1909 to 1913 inclusive), 20.2 per cent. failed; of the 43 who graduated previous to 1909, 25.6 per cent. failed, and of the 307 graduates of 1913, 15.3 per cent. failed.

The ninth column gives the rank of each state group of colleges according to the number of applicants. The Illinois group of colleges leads, having 914 graduates examined by state boards during 1913, followed by New York with 651, Pennsylvania with 540, Tennessee with 329, Missouri with 296 and Maryland with 267.

The tenth column gives the rank of each state group of colleges according to the success of the graduates at the state board examinations. It is interesting to compare the figures of these two last columns. While the Illinois group ranks first according to the number examined [illegible] the success of its graduates at examinations. [illegible] second as to the number examined, it ranks [illegible] ess of its graduates at examinations and while Pennsylvania ranks third as to the number examined, it ranks twelfth in the success of its graduates at examinations.

Totals for 1912 include figures for Pennsylvania not published last year.

Table C permits of an interesting study of medical schools from the point of view of state board examinations. For some colleges a marked improvement in teaching methods is apparent from the fact that while the percentages of failures are high for old practitioners, they are lower for recent graduates and still lower for graduates of 1913. Other colleges, however, show no improvement either for recent graduates or for graduates of 1913. In the latter a knowledge of these colleges, based on a careful study, which included inspections of the colleges, bears out what the figures of this table indicate, that some of these institutions are teaching medicine no better to-day than they did ten or more years ago.

Non-Recognition of Medical Colleges

Table D shows for each college the states in which its diplomas are not given unqualified recognition. Non-recognition is expressed by different terms in different states. Some boards list colleges as "in good standing" or "not in good standing," some give them as "reputable" or "not reputable;" in New York, full recognition is given only to colleges which are "registered," and in Michigan colleges are divided into groups, only those of Group I having full recognition. This table also shows the latest rating given to each college by the Council on Medical Education.

The information given in this table is from official correspondence, and the data have been carefully verified. From the point of view of a prospective student who may be selecting a medical college, the facts are simply astounding. The table shows that there are only 31 medical colleges which have complete recognition in all states! If the student has completed two or more years of work in a recognized college or university before he seeks entrance to a medical college, he may take his choice from among 33 other colleges; otherwise he will find that his diploma will not enable him to secure a license in six states. If he gets his medical training in one of the remaining 43 colleges, he will awaken on graduation to the fact that his diploma is not recognized in from 10 to 32 states!

NON-RECOGNITION OF MEDICAL COLLEGES

(Based on Table D)

Not recognized by licensing boards of	Number of Colleges
From 24 to 32 states	21
From 10 to 15 states	22
From 2 to 9 states	33
Fully recognized in all states	31
Total	107

Without the information published in Table D, these state board statistics would be not merely incomplete—they would be actually misleading. For example, in 1912, thirteen graduates of the Eclectic Medical University of Kansas City, Mo., were examined by the Arkansas Eclectic Board of Medical Examiners and all passed. None was examined elsewhere during the year, so the statistics showed no failures for this college during 1912, making it appear to

This table is especially interesting, since it gives data relating to the 42 larger medical colleges arranged according to the number of graduates examined. This allows of comparison between colleges having classes of nearly equal size. This time the Chicago College of Medicine and Surgery had the largest number, the position having been held by the College of Physicians and Surgeons of Chicago in 1912, 1906 and 1907. In 1908 Jefferson Medical College had the highest number examined. In 1909, 1910 and 1911 the University of Louisville Medical Department had the largest number examined. The first place from the standpoint of the number examined, however, does not always mean first place from the standpoint of scholarship. Note the [illegible].

Of the 15 colleges having 100 or more examined, 7 have [illegible] than 10, while 8 stand out prominently with large failure percentages of 10.9, 11.7, 13.5, 15.6, 17.3, 21.4, 25.4 and 35.4 [illegible] holds for five of the colleges even in respect to recent graduates (of 1909 to 1913 inclusive) as well as for the graduates of 1913. The three highest failure percentages are for Meharry Medical College, 35.4, Long Island College Hospital, 25.4 and the University of Louisville, 21.4.

Of the 27 colleges having between 50 and 100 graduates examined, 11 had failure percentages of less than 10; 5 had failure percentages between 10 and 20, and 11 had failure percentages above 20, the five colleges having the highest failure percentages being Leonard Medical School, 51.9; Birmingham Medical College, 39.2; New York Homeopathic Medical College, 35.0; American Medical College, St. Louis, 32.2, and Albany Medical College, 30.4.

The average percentage of failures for these larger colleges for graduates of 1908 and previous years was 22.6; for graduates of 1909 to 1913 inclusive (recent graduates), 13.8; for graduates of 1913, 9.2, and for graduates of all years, was 14.5. Of the 5,339 graduates of the 99 colleges in the United States which had graduates examined by state boards in 1913, these larger schools furnished 3,958 or 74.1 per cent.

In this table the graduates of each college who were examined in the state in which the college is located are grouped in one column, while graduates of that college examined in other states are in another column. For example under Massachusetts, this table shows that, of the 24 graduates of College of Physicians and Surgeons of Boston, who were examined by state boards during 1913, 9 were examined in Massachusetts, of which number 2 passed and 7, or 77.8 per cent., failed, while 15 were examined in other states, of which number 8 passed and 7, or 46.7 per cent., failed. This table shows that in the majority of instances the graduates have better chances of passing examinations in the state in which their colleges are located than they have elsewhere. This should always be considered in making comparisons between colleges. A low standard college, by having all its graduates examined in the home state, may sometimes show a lower percentage of failures than a college of much higher grade which has graduates examined by several states.

The heavy-faced figures give the results by states. The first column of heavy-faced figures preceded by the + and — signs, shows the differences between the percentages of examination in the home state and the examinations elsewhere. The plus sign indicates that graduates have better chances of success in the state where the colleges from which they graduated are located; the minus sign indicates that the chances are better elsewhere. The most marked variations in 1913 were in the examination of the graduates of the colleges of Georgia, 39.7 per cent.; Vermont, 35.9; South Carolina, 35.7; Indiana, 33.3; Wisconsin, 28.1, and California, 26.8, in all of which the chances of the graduates were better in the home state. The marked variations where the graduates' chances were better elsewhere were in Alabama, 28.1 per cent.; New Hampshire, 15.9; New York, 15.4 and Oregon, 14.3 per cent. The danger of forming hasty conclusions from these percentages taken alone, however, is very well shown by the figures for Indiana where there is one high grade school, where only 3 graduates were examined in "other states" and where the failure of one of them could have been accidental. More reliable are the percentages in Tennessee, Illinois, Pennsylvania and Missouri where larger number from larger groups of colleges were examined in "other states." The totals show that on the average the chances of success were 6.8 per cent. better if the graduate took the examination in the state where his college was located.

rank among the best teaching institutions in the country. How different the picture, however, when the facts are told that the Eclectic Medical University is not recognized in Missouri, its home state, and that the diplomas are not recognized in twenty-eight states!

There are 32 state licensing boards which are utilizing to some extent, at least, their legal power to refuse recognition to medical colleges which do not meet certain educational standards or which otherwise do not meet the requirements in the respective states. In the other 18 states, either the practice acts do not give the boards the right to enforce a requirement of reasonable standards, or else the boards are apparently not exercising their privileges. It is clearly evident that graduates of low-standard medical colleges which are not eligible for license in 32 states will flock to the other 18 states which have not removed recognition. These 18 states, therefore, will hereafter literally be the dumping-ground of the output of the low-grade medical colleges until needed legal powers are granted to the licensing boards or until those boards take action in the matter.

STUDY OF TOTALS AND PERCENTAGES

A study of totals and percentages as compared with previous years is of interest. The total examined in 1913—6,435—is the lowest number of candidates examined for license in any year since the compiling of these statistics began. The total examined in 1913 shows a decrease of 444 below 1912 and a decrease of just 1,600 below 1906, when 8,035 candidates were examined. Statistics regarding physicians licensed in the various states by reciprocity and by other methods are given in Tables I, J and K. By all methods—examination, reciprocity, under exemption, etc.—6,501 physicians were licensed during 1913, or 222 less than in 1912, and 1,364 less than in 1906, when 7,865 physicians were licensed.

Other deductions from the larger tables have been made and are presented in Tables E to H, which are worthy of careful study.

STUDY OF COLLEGES BY STATE GROUPS

Table E is based on the first three large tables and gives the results for the group of colleges located in each state. It shows what states are furnishing the largest number of physicians, and the failure percentages indicate what kind of training these colleges are furnishing so far as may be judged from the failures of their graduates before state boards. By comparing the percentages of the first column with the other columns it can be seen whether or not there has been any reduction in failures for graduates of recent years. Of the 33 states having medical colleges which grant degrees, 15 furnished 100 or more candidates examined. Of these 15 groups of colleges, 4 had failure percentages of less than 10 per cent.; 7 had failure percentages between 10 and 20, and 4 had over 20 per cent. of failures. The highest failure percentage was obtained by the North Carolina group with 40. Of the states having 100 or more candidates examined, however, the highest failure percentage was obtained by the Tennessee group, which had 30.1 per cent., followed by the Alabama group with 26.0 per cent., and the Georgia group with 23.6 per cent. of their graduates failing. Other deductions are given with the table.

STUDY OF LARGER COLLEGES

Table F is also based on the three large tables and gives the results of state board examinations as they affect the 42 largest medical colleges. Although these colleges represent 42.4 per cent. of the medical colleges in the United States having graduates examined, they furnished 74.1 per cent. of all the candidates for license coming from medical schools of the United States. This table show, however, that the graduation of large classes by a medical college does not prove excellence of teaching, since several colleges having 100 or more examined have very high failure percentages, and this holds true even for the graduates of 1913. In fact, the larger the college from the point of view of the number of students and graduates, the more serious is inferior teaching ability, indicated by a high failure percentage. In fairness to the medical student, and in the interests of the public, such schools should greatly strengthen their teaching facilities or reduce the size of their classes.

Altogether for these schools, 577, or 14.5 per cent., failed, as compared with 17.1 per cent. of failures for the 1,381 candidates from the 57 colleges having less than 50 each examined.

Besides the graduates of the medical colleges of the United States, 1,096 candidates were examined, made up of 58 grad-

This table gives the number of candidates registered and rejected by *examination by each state during each of the last five years. The last* four columns give the totals for the five years and the percentage rejected by each state.

Six states registered over 1,000 candidates by examination in the five years, these being California, Illinois, Massachusetts, New York, Pennsylvania and Tennessee. Over 2,000 were registered in only two states, Illinois and New York. Of the 1,424 candidates registered in Tennessee in the last five years, 591 or 41.5 per cent. were non-graduates.

The highest percentages of rejections were 52.0 in Mississippi, followed by Alabama, Oregon, South Carolina and Arkansas, with 41.1, 34.3, 32.3 and 31.5, respectively. The states marked with an asterisk (*) included non-graduates among those examined during the last five years, and for that reason would supposedly have higher percentages rejected. Such, however, was not the case in Tennessee. On the other hand, in several states the boards refuse to recognize certain colleges a eliminate many candidates prior to the examination by a ca scrutiny of credentials and as a result there are lower percentage failures at the examinations.

The lowest failure percentages were in Michigan, 1.8; Wyoming, Vermont, 4.3; Indiana, 4.5; Ohio, 4.7; Delaware, 5.9, and Iowa, 6 uates of Canadian colleges, 89 foreign college graduates, 698 graduates of miscellaneous colleges and 251 non-graduates. Of these 1,096 candidates, 386, or 35.2 per cent., failed.

Results in Home States and Elsewhere

Table G is of much interest, because it shows for each college the results of examinations in the state in which the college is located, as compared with the results of examinations in other states, where there is less possibility of local influence. Of all recent graduates examined in 1913, 2,746, or 56.4 per cent., took their license examinations in the states in which the colleges from which they graduated were located. Of this number 11.9 per cent. failed on the average, whereas, of the 1,420 candidates examined in other states, 18.6 per cent. failed. This would indicate that, as a rule, the student's chances of passing the license examination are better if he stays in the college's home state. In this connection it is interesting to note that no graduate of any of the colleges in the District of Columbia, in Michigan or Vermont failed in the examinations given in those states, although of the graduates of these colleges who were examined in other states, the failures of these groups of colleges were, respectively, 13, 11.8 and 35.9 per cent. There were no failures either at home or in other states for graduates of the colleges of Colorado, Iowa, Kansas or Minnesota. The student's chances for success at home and elsewhere were equal or nearly so in three instances, these being for the colleges of Illinois, Maryland and North Carolina; the student's chances were better in the home state in eighteen instances, while in seven instances the student's chances were better if he went to some other state.

Totals	4509	571	156	1223	42	6501

This table shows the total number registered during 1913 in each state by the various methods. The first three columns show those registered by examination; the first column showing the recent graduates registered, the second column, the old pr 1908 and previous years) and the third column. fourth column shows the number licensed fifth column shows those licensed under varic the practice acts, such as because of national of diplomas (New Mexico). It is interesting states which have registered large numbers examined very few old practitioners. The chie which has only recently begun registration under a practice act providing for the recognition of licenses granted in other states. The last column shows the total number of physicians registered by all methods in each state during the year. Only five states registered over 300 each, these being Illinois, 614; New York, 541; Pennsylvania, 366; Tennessee, 323, and Texas, 307.

Total Results for Five Years

Table H shows, so far as reports were obtainable, the number registered and the number rejected in each state for each of the past five years. A comparison of this table with the statistics in the last educational number of The Journal (Aug. 23, 1913, p. 602, Table 12), shows what would be expected, that the states having the largest number of medical graduates examined the largest number of physicians. Now, only one state, New Mexico, will register candidates on presentation of diploma, without examination. This table shows only those registered by examination. The next table (I) shows the total registered by all methods.

Total Registration in 1913

The tables thus far described have referred only to the results of examinations and to those registered on that basis. Table I, however, shows the total number who received licenses in each state, including those registered by examination, by reciprocity and under various exemption clauses. Altogether 6,501 physicians were registered by all methods during 1913, as compared with 6,723 in 1912, 6,824 in 1911, 7,352 in 1910 and 7,865 in 1906. By reciprocity or under exemption clauses, 1,265 were licensed in 1913 as compared with 1,257 in 1912, 1,246 in 1911 and 1,640 in 1910. Over 100 were registered by all methods in twenty-six states, over 200 in ten and over 300 in five, the largest numbers being registered in Illinois with 614, New York with 541, Pennsylvania with 366, Tennessee with 323 and Texas with 307. There were 156 non-graduates registered in five states, 121 (77.5 per cent.) having been registered in Tennessee, 19 in Massachusetts, 15 in Oregon and 1 in Colorado.

Table J gives those registered without examination on presentation of satisfactory credentials, which included a license issued by some other state. This is usually described by the term "reciprocity," which conveys the idea that the state which accepts the license of another must be granted the same courtesy by the state issuing the original license. The term does not well describe this method of registration, however, since some state boards consider it more fair to the physician to accept his credentials, if satisfactory, whether or not the state board issuing the original license returns the favor. In fact, the new practice act of California requires the acceptance of the licenses issued by any state if the *applicant's credentials are otherwise acceptable. Had not* reciprocal relations been established by the 41 states shown *in the table, 1,223 physicians, the majority of whom have been* in practice for many years, would have been compelled to undergo the ordeal of a second trying examination.

Reciprocity and Educational Standards

As formerly administered, reciprocal relations between some states tended to lower rather than to elevate educational standards, and this is still true in some states. A study of these statistics will show that in several instances such relations exist between states differing widely in their standards of education and in the methods and severity of their examinations. It can be seen, therefore, that a loosely administered provision for reciprocity provides a wide-open door through which unqualified candidates can obtain registration. There are some boards, however, which wisely reserve and exercise the right to reject any candidate who does not possess satis-

This table shows the number of physicians registered by each state through reciprocity during 1913. Reciprocity is not the best term to use, however, since some states, California and Colorado, for instance, register candidates who have satisfactory credentials including licenses, regardless as to whether the states issuing the original licenses reciprocate with them or not. Taking New York as an example, reading from left to right, the table shows that New York registered a total of 27 applicants through reciprocity during 1913, of which number 4 came from Delaware, 1 from Indiana, 13 from Michigan, 6 from New Jersey and 3 from Ohio. Reading from above downward, the table shows that 70 physicians left New York during 1913 and registered in other states under the reciprocity provision, of which number 1 registered in Arkansas, 4 in California, 3 in Colorado, 4 in Connecticut, 1 in Georgia, 9 in Michigan, 42 in New Jersey, 2 in North Carolina, 4 in Ohio and 1 in Utah. Texas leads, having registered 139 physicians through reciprocity in 1913, followed by Colorado, 89; New Jersey, 88; Ohio, 72; Michigan, 69 and Wisconsin, 68. It is interesting to note in what states the original licenses were issued. The table shows that of the 1,223 applicants registered through reciprocity 171, or 14.0 per cent., obtained their original licenses in Illinois and 86, the next largest number, were first registered in Pennsylvania. The states which furnished the next highest numbers were Oklahoma, 74; New York, 70; Michigan, 66; Missouri, 61 and Ohio, 50.

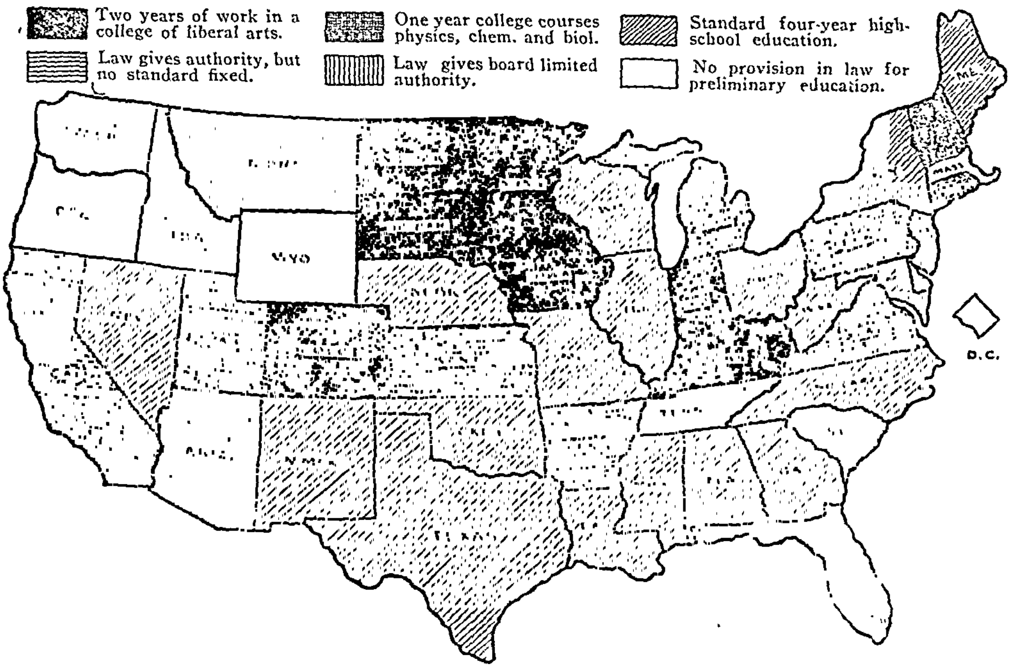
Totals	1167	1502	1128	1141	1223	6161

This table shows that 6,161 candidates were registered through reciprocity during the last five years. Registration by reciprocity has been gradually increasing although there was a drop in 1911. A study of the totals for the different states shows that of the 6,161 registered during the four years 1,206, or 19.5 per cent., obtained their original licenses in Illinois. This is more than twice the number coming from any other state. The states furnishing the next highest numbers are New York, 441; Missouri, 336, and Iowa, 318. The states marked with an asterisk (*) do not have reciprocal relations and would not appear in this table except for the fact that some states, like California, Colorado and New Jersey, will accept a physician's credentials if satisfactory, whether the state issuing his original license returns the favor or not.

factory credentials even though he is licensed in a state with which it has reciprocal relations. Some boards also prudently require that the applicant, before he is eligible to registration through reciprocity, must have been engaged in the actual and reputable practice of his profession for at least a year in the state in which the original license was granted. Without this provision a candidate may be tempted to obtain his original license in the state giving the easiest examination. Without the one-year residence clause, therefore, standards of examination are apt to be lowered. Again, some states wisely refuse to register by reciprocity any candidate who has failed to pass their own examinations. In the establishing of reciprocal relations, therefore, the state board should reserve and exercise the discretionary power to refuse to register any candidate who could not originally have registered in that state, and, secondly, the board should require that the applicant shall have been in actual practice of medicine for at least a year before he is eligible to registration under the reciprocity provision.

STATE REQUIREMENTS OF PRELIMINARY EDUCATION



Two years of work in a college of liberal arts.
One year college courses physics, chem. and biol.
Standard four-year high-school education.
Law gives authority, but no standard fixed.
Law gives board limited authority.
No provision in law for preliminary education.
WYO
ME.
D.C.

In the light of the foregoing statement in regard to reciprocity, it will be interesting to study Table K, which shows in what states the original licenses were granted of those who were registered elsewhere under the reciprocity provision during the last five years. It should be noted that of the 6,161 physicians licensed through reciprocity during the last five years, the original licenses of 1,206 (19.6 per cent.) were obtained in Illinois, more than twice as many as came from any other state. In New York 441 physicians took their original license examinations, 336 in Missouri, 318 in Iowa and 296 in Michigan.

The chart shows the standards of preliminary education for each state. There are 7 states, Colorado, Iowa, Indiana, Kentucky, Minnesota, North Dakota and South Dakota, in which the standard is two years of collegiate work; in 11 states the standard is one year of college work; and in 20 states the standard is a four-year high-school education. There are six states in which the law seriously divides the authority between independent boards, or where the standard is less than a four-year high-school education, while in four states, Massachusetts, Oregon, Tennessee, Wyoming and in the District of Columbia, the practice acts make no provision for preliminary education. Table L shows the states in which the boards have adopted the requirement of one or two years of collegiate work as a minimum. It is known that in several other states the adoption of these higher requirements in the near future is contemplated.

In Conclusion

In the publication of these statistics the endeavor has been to give an absolutely fair presentation of facts, a knowledge of which is always beneficial. Without question this annual presentation of the results of state licensing examinations has had a most helpful influence on medical education and medical licensure in this country. We reiterate our acknowledgments to the state licensing boards whose ready cooperation and complete reports have made the publication of these data possible.

TABLE L—STATE REQUIREMENTS OF HIGHER PRELIMINARY EDUCATION

There are now eighteen states which have adopted requirements of preliminary education in addition to a standard four-year high-school education. These states, the number of college years required and the time the higher requirement becomes effective are as follows:

State Examining Board of—	Number of Years Required	Affects Students Matriculating	Affects All Applicants
Minnesota	2	1908-09	1912
North Dakota	2	1908-09	1912
Colorado	2	1910-11	1914
Connecticut	1	1910-11	1914
Kansas	1	1910-11	1914
Indiana	2	1910-11	1914
Utah	1	1910-11	1914

STATISTICS OF STATE BOARD EXAMINATIONS

We publish this week, for the eleventh consecutive year, tabulated statistics based on examinations conducted by state medical licensing boards. This year, however, the matter presented includes other information having a direct bearing on state boards and on methods of registration. For example, Table D, showing in what states certain colleges are not recognized, although not based on the reports of examinations, has a very important influence on the results of those examinations and is absolutely essential in the forming of an accurate conclusion regarding any state board or any medical college. All the data published, however, are based on official reports, and the figures have been carefully verified, so that reliance may be placed on the facts presented. Reports were received from all state boards this year and the statistics are complete. This is in marked contrast with the statistics of 1903, when the publication of these data began. At that time reports from a large number of boards could not be secured for the reason that no permanent records of the examinations had been kept.

IMPORTANCE OF THESE STATISTICS

The casual reader glancing over the tables will probably not appreciate the conditions which make the publication of these data so important. Medical education and medical licensure in this country are controlled by the forty-nine individual states, each of which in these matters is legally independent of the others. In the forty-nine states there are forty-nine different practice acts, providing for about sixty different licensing boards, no two of which entirely agree in the details of the methods followed or the standards enforced. No legal provision exists in this country for a national control in these matters, for a coordination of standards or for a cooperation between the different boards. This lack of a national control, or of uniformity of standards and of effectiveness of methods, is a very serious matter. In some states the public is well protected against illiterate and incompetent doctors, while in other states, because of poor laws or political boards, the right to practice medicine is easily secured by any person, no matter how incompetent he may be. If a doctor has had his license revoked in one state for malpractice or other reasons, he promptly goes to another state, where he seldom fails to secure a license. If he is caught again, he as promptly transfers his allegiance to a third state. To correct these serious conditions, a greater uniformity of standards and effectiveness of methods was essential among state boards. Toward that end the American Medical Association since 1903 has been voluntarily collecting and publishing information such as appears this week. If there were a national control of the licensing of physicians in the United States, such as exists in practically every other country, it would not be necessary for the American Medical Association to do this work.

The various tables deserve careful attention. A few additional comments are worth while, and the reader is urged to make a further study by referring to the tables and the descriptive matter accompanying them.

FACTS REGARDING EACH STATE

These tables give valuable information regarding medical licensure in each state. For example, Tables A and B show the number of candidates who appeared for examination, the colleges from which they graduated, the number from each college who passed and the number from each who failed, the total number registered, the total number rejected and the percentage of candidates rejected. This table allows of comparison between the totals and the percentages of one state and those of other states. If a state board's examinations are unusually lenient for graduates of medical schools located in that state as compared with the results for the same colleges in other states, the fact will be shown in Table G. To decide whether a low percentage of rejections means "leniency" or not, the reader should note in Table D whether the board has *refused to examine* graduates of low-grade colleges. If the board examines the graduates of only high-grade colleges, a low failure percentage is to be expected. If, on the other hand, a board admits graduates of any and all schools, or perhaps also non-graduates, an unusually high failure percentage would be expected. If in the latter circumstances there is still a low failure percentage, then "leniency" is perhaps too mild a term. The total number of candidates examined, registered and rejected in the last five years by each board and the percentage of rejections are shown in Table H. This permits comparison not only of the figures of the last year with those of the four previous years, but also of the figures of one state with those of the others. Table I shows for each state the totals registered by all methods, by examination, by reciprocity and under exemption clauses. This table also shows the number of non-graduates licensed. Table J shows the number of candidates licensed by each state through reciprocity and shows in what states the original licenses were granted. Table K shows the total number of physicians from each state who, during the last five years, secured licenses elsewhere through reciprocity. Table L gives the eighteen states which have adopted higher standards of preliminary education and the dates when the higher requirements are effective. The preliminary standards of all states are shown in the chart.

FACTS REGARDING EACH COLLEGE

The tables also give much information regarding medical colleges. For example, Tables A and B show in what states graduates of each college were examined; they show the number who passed and the number who failed in each state, the total examined in all states, the number who passed, the number who failed, the percentage of failures and the number of states in which graduates of the college were admitted to examinations. In fact, Tables A, B and C permit a comparative study of medical colleges of much value in connection with any investigation of medical colleges. Table E shows for the group of colleges located in each state the total number of graduates examined in all states, the percentage of failures and the rank of each group according (1) to the number examined and (2) to the success of the graduates at the examinations. Table F furnishes an interesting study of the larger colleges — those having fifty or more graduates examined during the year — and allows of comparison between colleges of nearly equal size. The mere fact that a college has large classes is no indication that it furnishes a better medical training. In fact, the data in Table F show that usually the contrary is true. Before a conclusion is formed regarding any college it is highly important to note in Table D whether or not its graduates are refused examination in any states. A low-grade college may occasionally have a very low percentage of failures by having all its graduates appear before a lenient board. The examination results taken alone would seem to indicate good teaching methods. Such an erroneous conclusion is prevented, however, if it is found, as shown in Table D, that graduates of the college are not admitted to examination in from ten to thirty-two states. A fairly good college may occasionally have a high percentage of failures, especially if they are in states having more rigid examinations. It is seldom, however, that a well-equipped and well-conducted medical college will, year after year, receive as high as 15 or 20 per cent. of failures of its graduates at state licensing examinations. These statistics regarding colleges are very interesting, and throw an important side-light on the classification[1] of medical colleges of the United States prepared by the Council on Medical Education, which is based on an actual inspection of the colleges.

TOTAL REGISTRATION IN ALL STATES

These statistics show for each state the number of candidates coming not only from each medical school in this country, but also from Canadian and other foreign medical colleges. In short, they give an accurate record of the number and source of those who are entering the practice of medicine each year in this country. Without the data published this week, it could not be known that 6,501 physicians were licensed in this country during 1913, and that this included 5,236 who were registered by examination, including 156 non-graduates, 42 who were registered under the various exemption clauses, and 1,223, mostly old practitioners, who were registered under the provision for reciprocity.

STATISTICS ACCURATE AND RELIABLE

The work of collecting and publishing these statistics was begun by The Journal in 1903, but since the Council on Medical Education began active work in 1905, they have been developed as an important part of the Council's work. Every report received from the state licensing boards is now carefully checked, duplications are avoided, errors are corrected and the statistics are thereby rendered accurate and reliable. This is made possible through the enormous amount of data collected by the Council regarding medical colleges, students and graduates. Through the possession by the Council of complete alumni lists of all existing medical colleges, the Council is in position to avoid charging a college with a failure which may have been erroneously accredited to it when, in fact, the candidate who failed was a graduate of some other college.

INFLUENCE ON MEDICAL LICENSURE

These statistics have had a much greater effect, however, than that rendered by a mere numerical record of physicians examined and licensed, and probably no one has recognized their value more than the state licensing boards themselves. As a result, in many states splendid systems of record-keeping are now to be found where formerly, in several states at least, no records whatever were kept, and in several other states the systems were far from perfect. During the last several years, furthermore, they have furnished abundant argument for practical tests in state license examinations and have undoubtedly had much to do with the improved character of these examinations and the better methods of conducting them. A study of the statistics for several years will show that, although there has been a gradual improvement, there is still much that needs to be done.

INFLUENCE ON MEDICAL COLLEGES

The influence on medical colleges resulting from the publication of these statistics has been tremendous. Whereas previously these institutions may have been unaware of the weaknesses in their methods of teaching, these statistics have shown them how frequently their graduates fail at the state license examinations. There has been marked improvement in their equipment, better teachers have been secured and better methods adopted, and it can be seen by a review of the statistics published during the last several years that a number of colleges have materially reduced the failure percentages of their graduates at these examinations.

COOPERATION MUTUALLY ADVANTAGEOUS

As will be understood by the careful reader, these statistics have their greatest value when studied in connection with other data collected by the Council on Medical Education and published in THE JOURNAL and in the Council's reports. The state board statistics are made more accurate and reliable through the data kindly furnished by medical colleges; they are based on reports received direct from state boards; but through the careful checking of those reports, errors are frequently corrected, the state boards are notified and in this way state records are also made more accurate. The statistics published this week, therefore, have been made possible only through the cordial cooperation of both the state boards and medical colleges, and for this cooperation we again express our acknowledgments.

THE SOURCES OF DANGER IN ANTIMENINGITIS SERUM

Despite the undeniable success which has followed the antiserum treatment of cerebrospinal fever since its introduction as a therapeutic measure in 1906, important contributions that have appeared from time to time in THE JOURNAL[1] must serve to direct attention to the possible sources of danger from the administration of the serum. The papers referred to include reports of alarming symptoms and in a number of instances, death. The untoward results occurred in such close relation to the administration of the treatment that the latter, rather than the disease, seemed to be responsible.

To account for these accidents during the administration of the serum, various explanations have been advanced. Thus, at different times it has been asserted that these deaths were due to rapid lysis of the meningococcus and the consequent liberation of a toxic amount of bacterial toxin; to the production, through the introduction of large amounts of a foreign protein, of anaphylactic shock; to increased intracranial tension, from the too rapid or too free use of the antiserum, and the consequent interference with the vital centers, or to the presence in the serum of poisonous preservatives which were carried directly to the centers of respiration, with a resulting paralysis and death. Among these possible sources of danger, that attributable to sudden increase in intracranial pressure was promptly recognized. Precautions to avoid it are seen in the directions of Flexner and Jobling[2] to make the injection slowly and carefully, and previously to withdraw from the spinal canal at least as much fluid as the amount of antiserum to be injected. Furthermore, Koplik[3] favors the gravity method of introducing the serum rather than the syringe method.

Trikresol has been employed in this country as a preservative of the serum. This has been charged with toxic effects on the patients; but it must be noted that sudden deaths have been reported in cases in which the serum used contained no preservative. Dr. Worth Hale of the staff of the Hygienic Laboratory of the United States Public Health Service has lately undertaken to determine, by experiments on animals,[4] the responsible factors in the deaths from subdural injections of antimeningitis serum. From his studies it would appear that death from the introduction of the fluid may result either from an increase in intracranial tension or from the presence in the serum of trikresol. The danger from trikresol, however, seems much greater and more certain than that which may possibly arise from increased pressure, and on that account an effort should be made to discover a serum preservative which would not have the peculiarly toxic action of trikresol on the central nervous system. Failing in that, antimeningitis serum should be dispensed in sterile containers free from any preservative.

The practical outcome of the governmental investigation is found in the suggestion that blood-pressure observations should be made in every case in which cerebrospinal fluid is withdrawn or serum is introduced into the meninges. By this procedure, warning will be given of any possible danger either from increased intracranial tension or from the poisonous action of any of the serum preservatives. Further, also, it would seem much wiser to discard the syringe method of introducing serum in favor of the gravity method, which permits the use of much greater care and gentleness in making the administration.

As Hale and others have pointed out, the occasional undesirable effect of the serum treatment should not, however, be considered as militating against its regular and invariable use in all cases of the disease, for the dangers which may arise from the treatment are not to be feared in any such way as is the disease itself. The risk, as compared with that from the disease itself, is very small. Therefore too much emphasis cannot be laid on the advisability and importance of the early and free use of antimeningitis serum in all cases of epidemic cerebrospinal meningitis, even though occasionally its administration may be followed by untoward effects. Physicians will be glad to learn that work in developing a suitable preservative for serum is under way in the government laboratories.

PELLAGRA AND INFECTION

Any one who reads the current medical literature would be rash, indeed, to look on the problem of the etiology of pellagra as solved in any sense. Those who adhere to the view that corn in the dietary is in some way involved in the production of the disease are in turn divided in opinion as to whether the pathogenetic factor is of the nature of a nutritive deficiency in the corn regimen or is some toxic product developed under unusual conditions by biologic agencies in the cereal before it is eaten. If the zeists are thus uncertain among themselves with respect to the cause of pellagra, no greater accord exists among the not inconsiderable number of thoughtful persons who adhere to the theory of an infectious or microbiotic etiologic agency. Several commissions have already begun an extensive survey of the pellagra situation in this country and an investigation of the possible causative or contributory influences at work. Among the more recent ones the Thompson-McFadden Pellagra Commission of the New York Post-Graduate Medical School and Hospital has already published a preliminary report of its undertaking.[1] In this the following tentative conclusions are reached: The supposition that the ingestion of good or spoiled maize is the essential cause of pellagra is not supported by their study. Pellagra is in all probability a specific infectious disease communicable from person to person by means at present unknown. The commission has discovered no evidence incriminating flies of the genus *Simulium* in the causation of pellagra, except their universal distribution throughout the area studied. If it is distributed by a blood-sucking insect, *Stomoxys calcitrans* would appear to be the most probable carrier. They are inclined to regard intimate association in the household and the contamination of food with the excretions of pellagrins as possible modes of distribution of the disease. No specific cause of pellagra has been recognized.

Further light is shed on the foregoing views by observations recently related by Drs. Siler, Garrison and MacNeal of the commission.[2] A statistical study of the foods used and of the occurrence of pellagra in six mill-villages, including about 5,000 persons, failed to reveal any consistent relationship between the use of any particular food and the occurrence of pellagra. A somewhat similar statistical study of the location of domicile of old cases of pellagra in relation to domicile of the remaining population in these mill-villages has shown that new cases of pellagra developed almost exclusively in persons living in the same house in which such antecedent cases had occurred or in houses next door. In other words, the disease spread from a preceding or antecedent case as a center, a phenomenon which can be explained satisfactorily, in their opinion, only by assuming that pellagra is an infectious disease. Apparently, it is not readily transmitted to any considerable distance.

As was observed in the field studies, pellagra has spread most readily in communities in which unscreened surface-privies were in use. In those portions of the city of Spartanburg, S. C., equipped with a water-carriage system of sewage disposal, new cases of pellagra were relatively few. In two mill-villages completely equipped with a water-carriage sewer system, it was impossible to find cases of pellagra which had certainly originated there. Persons suffering from pellagra contracted elsewhere were not lacking in these communities.

With a further group of investigators from the United States Public Health Service in the field and other agencies at work on the problems of pellagra, it would be premature to issue a final verdict on a subject which has provoked such a diversity of opinion. Hence we merely present to our readers the latest contributions from reliable sources while awaiting that final accord of the findings which characterizes the successful result of scientific research.

SYMPTOMS IN CHRONIC MORPHINISM INDUCED BY WITHDRAWAL OF THE DRUG

Despite the interesting facts which have been developed in the past decade or more concerning the underlying features of chronic morphinism, a number of phenomena have been left unexplained. Our understanding of the remarkable tolerance to the alkaloid exhibited by the addict has especially been promoted by the researches of Faust,[1] who clearly demonstrated that the organism habituated to morphin develops an increasing capacity to destroy it. He found, for example, that after a single injection of this substance in animals, about 70 per cent. of it could be recovered through the usual channels of excretion—the stomach and intestine. With repeated and gradually increasing dosage, on the other hand, the quantity of morphin found in the feces lessens until finally, even when doses lethal to the unaccustomed subject are administered, no morphin whatever may appear in the excretions. Inasmuch as on analysis the organs were found under such circumstances to contain only very small amounts of the

---

[1] Faust, E. S.: Arch. f. exper. Path. u. Pharmakol., 1900, xliv, 217.

alkaloid, Faust logically concluded that in developing a tolerance to it the organism acquires a capacity to destroy far greater quantities of morphin than it originally possessed.

This cannot completely explain the decreasing sensitiveness of the morphinomaniac to the drug. Even when morphin is subcutaneously administered and thus promptly reaches the blood-stream for distribution the addict is unduly tolerant to large doses. It cannot be assumed that this is due solely to an acquired power of rapid destruction (within a few minutes); for this would mean an almost inconceivably accelerated detoxication of the substance. Rübsamen[2] has observed that rats which are gradually immunized to large quantities of morphin and which can take double the usual lethal dose with impunity, may, at a given moment, show the presence in their bodies of an amount of the alkaloid sufficient in itself to produce toxic effects in an untreated animal of the same species. He therefore assumes that the body develops not only an increased power of destroying this drug, but also a greatly diminished cellular sensitiveness to its action.

Important as these aspects of the continued use of morphin doubtless are for an understanding of the altered physiologic conditions it produces, they furnish no clue to an added feature which must be taken into account in practice. The sudden withdrawal of the drug does not result merely in negative symptoms, but often produces such intense misery and depression as to indicate actual danger. There are positive manifestations which it is difficult to explain solely by the lack of the narcotic, so that something more than the mere staying of the craving appears to be necessary. These after-effects have been attributed variously to the presence of remaining derivatives of morphin which are assumed to be especially toxic.

Perhaps a step toward a final explanation of the depressive symptoms of the withdrawal stage after chronic morphinism is to be found in the recent work of Adriano Valenti[3] at the institute for experimental pharmacology in the University of Pavia. When morphin administration to dogs is stopped after a period of developing immunity, the animals show marked circulatory disturbances—increased frequency of the pulse, severe arhythmias, and arterial hypotension—which promptly disappear if morphin is again administered until the so-called morphin pulse manifests itself. More significant is the fact that when the serum of dogs habituated to large doses of morphin and then suddenly deprived of it is injected into normal animals of the same species, the foregoing syndrome is promptly produced. This is not due to a toxic influence of the serum as such; for the ill effects are not seen when the serum of unmorphinized dogs is introduced. The severity of the symptoms stands in direct relation to the size of the morphin intake to which the donor of the serum has previously been accustomed. Such observations widen the field and open new avenues of approach to the cause of the withdrawal symptoms. Obviously the lack of morphin is not the sole determining factor.

THE SOURCE IN THE FLUIDS IN SYPHILIS OF THE SUBSTANCES WHICH GIVE THE WASSERMANN REACTION

The source and the nature of the substances in the blood and other fluids of syphilitics on which the Wassermann reaction depends are not determined. At first they were regarded as true antibodies, but when it became known that specific antigen (extract of congenitally luetic liver) is not essential in order to obtain the reaction, and that the *Spirochaeta pallida* cannot be used successfully as antigen in the reaction, there no longer was any good reason for regarding the reacting substances in syphilitic fluids as of necessity being antibodies.

To obtain some clue as to the source of these substances, Wassermann and Lange[1] have made some very interesting experiments with the cerebrospinal fluid of syphilitics. They selected this fluid for their work because it is much less complex in its composition than the blood-serum and consequently less liable to undergo physicochemical changes that may give rise to misleading results. Thus the action of cerebrospinal fluid which gives the Wassermann reaction remains constant for a much longer time than in the case of serum. Wassermann and Lange find by accurate quantitative determinations that one source at least of the reacting substances is the lymphocytes in the fluid. It will be recalled that when the cerebrospinal fluid gives the Wassermann reaction it invariably contains an increased number of these cells, and it was found that autolysis of the lymphocytes in positive cerebrospinal fluid from syphilitics in most cases would result in an increase, sometimes very marked, in the power of the fluid to fix complement in the presence of extracts of syphilitic liver. This increase could not be obtained by autolysis of the cells in other cellular cerebrospinal fluids (those from non-syphilitic meningitis, alcoholic dementia) than those from syphilitics; hence it would seem that the lymphocyte, which is a prominent element in all syphilitic lesions, constitutes a laboratory for the manufacture of the substances necessary for the Wassermann reaction.

Whether these substances are antibodies still remains an open question concerning which Wassermann and Lange indicate that they may have something to say before long.

Current Comment

PROSPECTIVE MEDICAL STUDENTS AND LOW-GRADE MEDICAL COLLEGES

One of the tables published this week[1] (Table D) shows the states in which the diplomas from certain colleges are not given unqualified recognition. The table indicates that in from fourteen to thirty-two states the diplomas issued by thirty medical schools are not recognized, and that in these states the graduates of these thirty schools are not admitted to the examinations for licenses to practice medicine. It is highly important that this information should receive wide publicity, particularly in the interests of prospective medical students. Before selecting a medical school the student should know whether the training furnished and the diploma given by that school will qualify him for examination and for a license to practice medicine in any state he may choose. This information, that is, the fact that recognition has been withdrawn or withheld from certain medical colleges, is not always given publicity by state boards and, of course, is not published in the announcements of the colleges affected. Some students, therefore, have not been aware of the conditions until they had matriculated, or even until the time they had applied for a license to practice. Hundreds of students, in fact, have enrolled in low-grade medical colleges, have spent large sums of money, and have devoted three or four years to study, or have graduated before they learned these facts: not only that they have not received a training in modern medicine, but also in in many instances have received diplomas which in a large number of states are worthless. This is positively wrong and places a life-long handicap on these students. The important information regarding the non-recognition of low-grade medical colleges by state boards should be in the hands of every prospective medical student when he chooses his college. This knowledge will enable him to avoid the serious mistake of making a bad start on his life's work. The intelligent student, thus informed, would certainly not waste his time and money in a low-grade institution when, in the same time and with perhaps even less money he could obtain a training in a thoroughly well-conducted medical school which would not only better equip him for his profession, but would also enable him to render better service to the people who will depend on him for medical attention or hygienic instruction.

THE PUBLIC AND LOW-GRADE MEDICAL COLLEGES

The information published in Table D is especially of importance to the public: it indicates the states that are not adequately protected against untrained doctors. The table shows that the boards of thirty-one states are making use of the legal power conferred on them to discriminate between medical colleges and to refuse recognition to those which are of low standard or are not properly equipped to furnish their students a satisfactory training in modern medicine. Of the thirty-one state boards, seven[1] will not license the graduate of any medical college unless he had completed at least two years of work in an approved liberal arts college before taking up the study of medicine. There remain eighteen states in some of which the boards do not have legal authority to pass on the character or standing of the colleges whose graduates may be admitted to examination. In other states the boards are apparently given ample powers, but, so far as our information shows, are not using those powers. It is important to note, that since the graduates of these low-grade medical colleges cannot secure licenses in thirty-one states they will flock to those in which they are still eligible. These eighteen states, therefore, are certain to be the dumping-ground for the output of these inferior colleges just so long as the practice acts permit, or so long as the state licensing boards do not take action against them. The people have the right to expect that the state — on which the national constitution places the responsibility — will grant them proper legislation, and that the licensing board — the only legal body having these matters in charge — will take such action as is necessary to protect them against the ill-trained product of low-grade medical colleges.

STREPTOTRICHAL ORGANISMS IN THE SPLEEN IN CERTAIN CASES OF SPLENOMEGALY

Certain cases of splenomegaly, especially those which Osler classifies under the term of "splenic anemia," have many features suggestive of parasitic infection. The semblance to kala-azar and the beneficial effects following splenectomy and the administration of such remedies as salvarsan have frequently been noted, but thus far no specific etiologic factor has been determined. In an exhaustive study of the spleens from six patients A. G. Gibbons[2] found evidences of a streptothrix invasion in such relation to the tissues as to suggest this as the cause of the enlargement and fibrosis. These cases fall into two groups, four in the first group and two in the second, suggesting that there might be two different varieties. In a typical case of Banti's disease representing the first group in which special attempts were made to find parasites, the spleen was greatly enlarged and its capsule irregularly thickened. Small recent infarcts were present. Throughout the spleen were areas with branches of yellowish but not calcified material. After staining by Wheal and Chown's method, which, briefly, is a double stain, first by hematoxylin, then by carbol-fuchsin, the decolorization being effected by equal parts of alcohol and saturated watery picric acid, black masses appeared in the trabeculae close to the veins, corresponding to the yellow areas of the fresh specimen. Under high power these masses consisted of numerous threads, and individual fibers averaging

[1] Page 1650.

[1] These states are Colorado, Iowa, Indiana, Kentucky, Minnesota, North Dakota and South Dakota.

[2] Gibbons, A. G.: On the Infective Nature of Certain Cases of Splenomegaly and Banti's Disease, Quart. Jour. Med., January, 1914, p. 153.

0.25 micron in thickness were seen only at the edges of the masses. The threads appeared segmented, in some places assuming a bacillary form with rounded ends; in other places where the threads were thicker and had undergone hyaline changes they were granular. A noticeable feature was the constancy with which the black masses were associated with the vessels. In some cases the walls were invaded and a beginning thrombosis was present, but the masses never penetrated into the lumen. The veins not affected were fibrous, suggesting a healed focus of previous invasion. In the second group of cases, stained sections showed a brilliant-red fine mycelium-like network occurring in round or oval masses. These masses formed a network of branches and threads varying in thickness and presenting different pictures, some ending in bulbous club-shaped extremities, others, separated from the network, appearing as cocci and short bacilli. By various stains the possibility that some tissue structures had simulated the parasites was eliminated. The masses were Gram-negative and were not acid-fast. Cultures were made on agar and blood-agar from the splenic pulp in only one case but without any results, the other spleens having been preserved some time before they were examined. These observations are hopeful as indicating progress in our knowledge of the conditions associated with splenomegaly; further evidence, however, must be obtained before definite conclusions can be drawn.

VARIATIONS IN THE PATHOGENIC AND OTHER CHARACTERISTICS OF SPIROCHAETA PALLIDA

Knowledge of the morphology and pathogenic characteristics of *Spirochaeta pallida* has reached the stage at which observers are attempting to classify distinct strains, the differentiation of which depends on definite variations in form, pathogenic power, virulence, etc. Noguchi[1] describes three types of the organism: the thick, thin and medium forms. Nichols[2] reviews the observations of others and contributes a study of a type of organism frequently found in syphilis of the central nervous system. The strain studied was isolated from the cerebrospinal fluid of a patient with nervous syphilis, and conformed to Noguchi's thick type in form. It produced in the testicles of rabbits a distinct lesion with raised indurated margins and necrotic centers, and localized constantly on the scrotal side of the tunica vaginalis. The incubation period averaged eighteen days, while that of the corresponding type of Noguchi averaged five weeks. What Nichols considers the most striking differential feature in this strain is its tendency to generalize, with lesions of the skin, eye and opposite testicle secondary to the inoculation lesion in the one testicle. These observations lead the author to conclude that he is dealing with a peculiar strain whose chief characteristic is its "invasive power" or what is described by others as high virulence and selective preference for certain tissues. He cites *Spirochaeta pertenuis* as an example of an organism of low invasive power. This organism produces yaws, which is a non-venereal, non-hereditary skin disease, and is not known to invade other tissues. For this reason Nichols suggests a classification with the *S. pertenuis* at one extreme, and the highly invasive strain isolated by him at the opposite extreme of the series, other strains occupying intermediate positions according to their characteristics. We have recently commented[3] on variations in the cultural, morphologic and pathogenic properties of certain bacteria, as observed by different workers, and it would seem that the same biologic principles there suggested might apply to organisms of the syphilis group, namely, that organisms of a given species may vary in their characteristics according to their environment either *in vitro* or *in vivo*, and with this variation may exercise a selective preference for different tissues and manifest varying grades of pathogenic power.

EFFECT OF THE VANDERBILT DECISION ON MEDICAL EDUCATION IN THE SOUTH

The Supreme Court has recently decided that the board of trustees of Vanderbilt University, and not the General Conference of the Methodist Church, has the authority to select those who are to fill vacancies on that board. As a result of this decision the medical department of Vanderbilt University has secured the gift of one million dollars offered about a year ago[4] by Mr. Carnegie, and this, in turn, permits a continuation of the remarkable development already well begun in that school whereby it will continue to hold its place among the best medical schools in this country. Vanderbilt University Medical Department has had a long and difficult fight to uphold fair standards of preliminary and medical education against perhaps more numerous and embarrassing handicaps than have confronted any other medical school, and for that reason its recent good fortune is all the more gratifying. Even though it is located in the state which at present has the weakest legal requirements regulating the practice of medicine, it is now in position not only to maintain high standards in medical education in that state, but also, in the administration of its entrance standards, to exert a splendid influence in general education throughout the entire South.

Prevention of Drunkenness.—As long as intoxicating liquors or other intoxicating drugs are accessible to persons who are mentally defective, to persons of weak will, or to persons of normal mentality who suffer marked physical discomfort or pain because of overwork, undernourishment, unemployment, illness, or domestic and business worries, there is likelihood that any use of alcohol will lead to its abuse. In so far, therefore, as evil heredity, bad housing conditions, long hours of labor, poverty and other predisposing causes can be reduced gradually through preventive legislation, the sources of inebriety of the pathologic type will be correspondingly diminished.—Report of Commission to Investigate Drunkenness in Massachusetts.

Medical News

ARIZONA

Personal.—Dr. Guillermo R. Servin, Tucson, has been appointed consul of the Republic of Mexico at Mexicali, Cal.

State Health Officers Elect.—At the third annual meeting of the Arizona Association of State and County Health Officers held in Tucson, April 24. Dr. George D. Troutman, Tucson, was elected president, Dr. Henry A. Hughes, Phoenix, vice-president, and Dr. Robert N. Looney, Prescott, secretary.

CALIFORNIA

Austrian Surgeon at Riverside.—At the annual meeting of the Southern California Medical Society, held at Riverside, May 7 and 8, Dr. Egon Renzi, Vienna, Austria, delivered an address on "Extirpation of the Spleen for Anemia."

The Foresters Sanatorium.—Among the sanatoriums established in the West by various benevolent and secret orders for the care of their members afflicted with tuberculosis, is that of the Foresters recently erected in Lopez Canyon near San Fernando, about 25 miles from Los Angeles. Dr. Clarence B. Dickson, Los Angeles, chief ranger of the order in California, has donated his services as physician for the first two years. The sanatorium has quarters for about fifty patients, and is arranged on the cottage plan, with separate living quarters for nurses, with power plant, dairy, etc.

CONNECTICUT

New Officers.—Litchfield County Medical Association at Winsted, April 28: president, Dr. Elias Pratt, Torrington; secretary, Dr. C. H. Turkington, Litchfield.

Board of Health Appointments.—The following roster of the New Britain Board of Health is announced: Drs. Arvid Anderson, George H. Bodley and Henry T. Bray; Messrs. M. W. Davenport, Herbert S. Tallard and Timothy E. Burns. Dr. Thomas E. Reeks has been appointed health officer of the city.

State Epileptic Colony Opened—The Connecticut Colony for Epileptics at Mansfield opened for the reception of patients May 15. The colony is located on a tract of land 500 acres in extent on the summit of a slope overlooking the Willimantic River, and will have accommodation for eighty patients and the necessary attendants and workmen. Dr. Donald L. Ross has been in charge of the construction, and will be superintendent of the institution. Dr. Max Mailhouse, New Haven, is president, and Dr. John H. Mountain, Middletown, vice-president of the board of trustees of the institution.

ILLINOIS

New Clinical Laboratory.—The Illinois Valley Clinical Laboratory has been established at Ottawa under the supervision of Dr. Roswell T. Pettit, with J. B. Gookin, formerly of Chicago, as chemist and bacteriologist.

Consulting Staff for State Hospital.—Superintendent H. J. Gahagan of the Elgin State Hospital has appointed the following complementary medical staff: eye, ear, nose and throat, Dr. John R. Tobin; gynecology, Dr. Frederick C. Schurmeier; internal medicine, Dr. John F. Bell; dermatology, Dr. Edward H. Abbott, and pathology and bacteriology, Dr. Samuel L. Gabby.

Personal.—Dr. Oscar B. Edmundson, Clinton, has purchased an interest in the Sulphur Springs Sanitarium, Peoria. ——Dr. James A. Rutledge, Woodmen, Colo., formerly of Elgin, has been elected state consul for the Colorado Woodmen of America.——Dr. A. M. Shaw has been appointed health commissioner of Clearing, and Dr. Orlando F. Scott, health commissioner of the villages of Summit, Argo, Justice and Gary.

Expense of State Charitable Institutions.—According to the statement of Frank D. Whipp, fiscal supervisor, State Board of Administration, the total expense of caring for the 20,000 inmates of the various state institutions for the year ended June 30, 1913, was $4,445,815.93. Of this amount $3,395,012.40 was for ordinary operating expenses, and $1,050,803,53 was for the upkeep of buildings and plants, the erection of new buildings and for permanent improvements. The largest item was for salaries, $1,492,853.75, which includes the wages of all employees. For medical supplies the sum expended was $46,041.11. After deducting amounts paid to the state by relatives of inmates for support, sale of farm products and other income not from the state treasury, the average net per capita cost of maintenance of the inmates of all classes of institutions was $158.37. The average net per capita cost of maintaining the insane was $142.24; feeble-minded, $156.09; deaf, $314.15; blind, $308.09; industrial home for the blind, $303.56; Soldiers' Home, $157.87; Soldiers' Widows' Home, $373.32; Soldiers' Orphans' Home, $261.56; Eye and Ear Infirmary, $273.77; school for girls, $199.30, and for inmates of the boys' school, $258.05.

Chicago

Personal.—Dr. and Mrs. Arthur W. Stillians sailed for Europe, April 25.——Dr. Otto L. Schmidt was reelected president of the Illinois State Historical Society at its meeting in Springfield, May 8.——Dr. Julia D. Merrill died May 17. Further notice will appear next week.

Infant Welfare Fund.—Great progress is being made in the collection of funds by the organizations interested in the infant welfare movement. One forenoon's work brought $4,513.70 to the association. Mr. Julius Rosenwald has promised to add 25 per cent. of the total sum collected. The campaign will end May 23d, when a complete report will be made.

Pathological Society Elects.—At its annual meeting, May 11, the Chicago Pathological Society elected the following officers: president, Dr. Ernest E. Irons; vice-president, Dr. L. E. Day; secretary, George H. Weaver; treasurer, Alexander A. Goldsmith; censors, Drs. Evarts A. Graham, Walter W. Hamburger and Frederick R. Zeit; and publication committee, Drs. Ludvig Hektoen, H. Gideon Wells and Frederick R. Zeit.

Clean-Up Week.—The Chicago *Health Bulletin* in commenting on the annual clean-up week, through which Chicago has just passed, says that the good feature about it is that it inculcates not only the clean-up spirit, but the keep-clean spirit, and this is the spirit that counts. In this connection it is suggested that as one means of keeping the back yard in good condition, there should be enough gardens in Chicago to supply thousands of tables with fresh vegetables.

Nurses' Training School Renews Contract.—The county board has refused to pay for $8,400 worth of nursing service supplied this year to the sick and injured in the county hospital. The service was supplied by the Illinois Training school. The board has renewed its contract with the school. A plan will be devised for financing the nursing until the county commissioners decide to pay and an appeal to the public for subscriptions is probable. The contract awarded provides the school shall have $45.85 a nurse actually employed.

Deaths from Accident During 1913.—Falls were the source of the greatest number of deaths from accident in Chicago last year, according to figures compiled by the Health Department. The total number of deaths from accident was 1,925. The chief causes were as follows: falls, 333; burns, exclusive of those caused by blazes in buildings, 291; railway accidents (steam), 271, street, 157; illuminating gas, 133; drowning, 122; automobiles, 121; poisoning, 42; electricity, lightning excepted, 24; due to machinery, 62. Of the 216 homicides reported during the year 135 were caused by firearms and 27 by stabbing or cutting. There also were 497 cases of suicide investigated by the coroner's office.

Good Housing Organization Formed.—Incorporation papers were taken out May 19 for the Chicago Housing Association. The first meeting of the new association will be held May 21, when a dinner will be given for Robert W. de Forest of the Russell Sage Foundation, president of the Housing Association of the United States.

The speakers will be Mr. de Forest, Mrs. Emmons Blaine, Dr. Charles R. Henderson, Dr. W. A. Evans, Miss Jane Addams, Miss Mary McDowell and others.

The association was formed of the housing committees working toward better housing conditions in Chicago of all organizations. The object was to get one organization with a concentrated effort, eliminating all duplication. The Chicago Association of Commerce, the City Club, the Woman's City Club, the Chicago Woman's Club and other civic organizations are represented in the board of directors of the association.

Clean Water Bill Offered for Protection of Chicago.—It is likely that pollution of the water-supply of Chicago and other lake cities by the sewage discharged from vessels will be prohibited in the near future. A bill, approved by the United States Public Health Service, was introduced in the House of Representatives, May 19, by Representative Mann of Illinois.

The bill provides: That no common carrier operating vessels, craft, or other vehicles or structures for the purpose of navigation shall discharge or cause to be discharged sewage or any other noxious material into the waters of the great lakes so as to pollute water-supplies of cities or towns or of other vessels plying on the great lakes; that no common carrier operating on the great lakes shall provide on steam vessels for the use of their crews and passengers water-supplies containing organisms or materials likely to cause disease of man.

For violation of the law an offender may be fined not more than $500 or imprisoned for not more than two years, or given both penalties.

IOWA

Personal.—Dr. George H. Stanger, Boone, who has been seriously ill, is improving and has resumed practice.——Dr. Cora Williams Choate has been elected president of the library board of Marshalltown.

New Officers.—Tama County Medical Society at Toledo, May 1: president, Dr. Albert A. Crabbe, Traer; secretary-treasurer, Dr. Frederick W. Gessner, Dysart.——Clayton County Medical Society at McGregor. April 29: president, Dr. Charles W. Duffin, Guttenberg; secretary-treasurer, Dr. William H. Thomas, McGregor.——Crawford County Medical Society at Denison, April 20: vice-president, Dr. William A. Garner, Kiron.——Harrison County Medical Association at Logan, May 7: president, Dr. John L. Tamisiea, Missouri Valley; secretary, Dr. H. Hansen, Logan.——Fremont County Medical Society, April 30, at Sidney: president, Dr. Theodore C. Harris, Tabor; secretary-treasurer, Dr. Ambrose E. Wanamaker, Hamburg.

KANSAS

New Officers.—Seventh District Medical Association at Hutchinson, April 24: president, Dr. William F. Fee, Meade; secretary-treasurer, Dr. William F. Schohr, Hutchinson.

Joint Meeting of Societies.—The joint meeting of the McPerson and Salina Counties Medical Societies held at Lindsburg, April 22, was so successful that it was voted to hold joint meetings every two months in that city.

Personal.—Dr. John De M. Miller, Leavenworth, returned from Europe, May 3.——Fire at Richmond, April 29, destroyed the office of Dr. Delmar H. Smith.——Dr. Lewis A. Ryder, Topeka, has been reelected medical director of the Home Mutual Life Insurance Company.

State Society Meeting.—At the annual meeting of the Kansas Medical Society, held in Wichita, May 5-7, the following officers were elected: president, Dr. William F. Sawhill, Concordia; vice-presidents, Drs. Jacob F. Gsell, Wichita; John F. Hassig, Kansas City, and Jacob L. Everhardy, Leavenworth; secretary, Dr. Charles F. Huffman, Columbus (reelected), and treasurer, Dr. Lewis H. Munn, Topeka (reelected). The society adopted a resolution asking the governor to appoint a commission to prepare a bill to be brought before the next legislature, defining the practice of medicine, and the requirement for practicing "the art of treatment of disease." Kansas City was selected as the place of meeting for 1915.

MARYLAND

Medal to Dr. Remsen.—Dr. Ira Remsen, formerly president of Johns Hopkins University and chairman of the Remsen Referee Board, was given a banquet by the Chicago section of the American Chemical Society, May 15, at which he was presented with the Willard Gibbs medal. This is the fourth award of the medal, and the third time it has been awarded to an American chemist. The presentation address was by Professor Noyes of the University of Illinois, and Dr. Remsen, in his response, spoke on "The Development of Chemical Research in America."

Physicians' Jubilee.—The Carroll County Medical Society gave a dinner on May 13 in honor of four of its members who have been in active practice for fifty years—Drs. George H. Brown, New Windsor; James H. Billingslea, Westminster; James Watt, Union Bridge, and John F. B. Weaver, Manchester. The first three of these physicians are graduates of the Maryland University, class of 1864. Dr. Daniel E. Stone of Mt. Pleasant, Frederick County, of the same class, was also present. Dr. Daniel B. Sprecher, Sykesville, president of the society, presided and acted as toastmaster.

Convention of Societies for Mental Hygiene.—The first convention of the societies for mental hygiene to be held under the auspices of the National Committee for Mental Hygiene will take place in Baltimore, May 25. The opening address will be delivered by Dr. Lewellys F. Barker, President of the National Committee for Mental Hygiene. Miss Julia Lathrop, Chief of the Children's Bureau, will speak on "What the Mental Hygiene Societies Ought to Do for Children." Hon. George P. McLean, U. S. Senator from Connecticut, will address the congress on "The Conservation of Mental Health—a National Problem," and Dr. William H. Welch, Vice-President of the National Committee, will speak on "Some Opportunities for the National Committee for Mental Hygiene."

Personal.—After serving as surgeon of Troop "A" Maryland National Guard, since its organization sixteen years ago, Dr. Charles G. Hill, Baltimore, has been placed on the retired list.——Dr. John H. Drach of Butler, Baltimore County, has been appointed health officer of the eighth district of Baltimore County to fill the vacancy caused by the resignation of Dr. William C. Ensor of Cockeysville.——Dr. Nathan R. Gorter, Commissioner of Health, has appointed Dr. Wilbur P. Stubbs, who has been examiner of throats for the department for a number of years, medical examiner of schools, to fill the vacancy caused by the death of Dr. Richard A. Urquhart.——Dr. Winford H. Smith, superintendent of Johns Hopkins Hospital, will return next week from California, where for the last two months he has been supervising the planning of the million dollar hospital for the University of California.

For Accurate Medical News.—At a meeting of the Baltimore City Medical Society held May 15, announcement was made of an agreement between the members of the publicity committee of the society and the press of the city relative to the publication of medical news. The agreement provides that in the future the representatives of the medical societies of the city cooperate with the representatives of the newspapers in communicating medical news accurately. The committee urges that wherever possible physicians give reliable information on important discoveries, the condition of patients of prominence and on other medical subjects in which the public is interested or which will tend to the public welfare. The names of no medical men are to be used by the newspaper unless written permission is given by the men whose names are used in the news items. Nothing is to be done that will be prejudicial to the interests of the patient or to other parties concerned in the items. The newspaper men agree to seek their information from the proper sources, that accurate information may be obtained. The agreement was adopted by members of the societies and committees were appointed on the various subjects of medical interest on which the newspapers may seek information.

MASSACHUSETTS

Anti-Vaccine Bill Defeated.—The bill passed by the Senate for eliminating the present requirement that children must be vaccinated before they are admitted to the public schools has been defeated by a vote of 132 to 53.

Personal.—Drs. James J. Minot and John F. O'Brien have been elected members of the building committee of the Boston Consumptives Hospital.——The action of the Boston Board of Health in removing Dr. William H. Davis, its vital statistician, has been rescinded.

New Officers.—Essex North District Medical Society at Lawrence, May 6: president, Dr. Israel J. Clarke, Haverhill; secretary-treasurer, Dr. J. Forrest Burnham, Lawrence.——Berkshire District Medical Society at Pittsfield, April 30: president, Dr. Franklin C. Downing, Lanesboro; secretary, Dr. Oliver L. Bartlett, Pittsfield.

Governor Approves State Health Office.—A special message was sent to the legislature by Governor Walsh, May 4, together with a bill which provides for the reorganization of the State Board of Health with one paid official, to be state health commissioner, and six unpaid assistants, including two engineers, two physicians, one sanitary expert and one lawyer.

MICHIGAN

Clinic for Babies and Young Children.—A free clinic for the treatment of babies and young children was opened at the Salvation Army Citadel, Flint, May 2. The clinic is to be held Wednesdays and Saturdays, and deserving cases will be cared for free of charge.

Changes in State Board.—Dr. John L. Burkart has succeeded Dr. Robert L. Dixon as secretary of the State Board of Health. Dr. Dixon has been appointed superintendent of the Michigan Epileptic Farm Colony, Wahjamego.——Dr. Marinus L. Holm is continued as bacteriologist of the State Health Department.

Personal.—Dr. Harry A. Wilson, Lansing, who has been ill at his home, has recovered and resumed practice.——Dr. Bret Nottingham, Lansing, is reported to be critically ill with cancer of the stomach at Harper Hospital, Detroit.——Dr. Edmund M. Pease, of the staff of the Michigan State Hospital, Kalamazoo, has accepted a similar position at the Massachusetts State Hospital, Boston.

State Medical Inspectors Appointed.—Dr. John L. Burkart, Lansing, secretary of the State Board of Health, announces the following list of medical inspectors for the State of Michigan, to conform to the recent congressional redistricting: First district, Dr. Guy L. Kiefer, Detroit; Second district, Dr. James F. Breakey, Ann Arbor; Third district, Drs. Alvin H. Rockwell, Kalamazoo, and Walter H. Sawyer, Hinsdale; Fourth district, Drs. Charles N. Sowers, Benton Harbor, and Dr. John McGuffin, Hastings; Fifth district, Dr. Thomas M. Koon, Grand Rapids; Sixth district, Dr. Henry S. Bartholomew, Lansing, and Dr. Don D. Knapp, Flint; Seventh district, Drs. William H. Smith, St. Clair, and Charles B. Morden, Bad Axe; Eighth district, Drs. Harold A. Hume, Owosso, and Fred A. Johnson, Greenville; Ninth district, Drs. George S. Williams, Muskegon, Julius M. Wilhelm, Traverse City, and George O. Switzer, Ludington; Tenth district, Drs. Edward Goodwin, Bay City, S. Elston Hooper, West Branch, and William T. Dodge, Big Rapids; Eleventh district, Drs. William H. Marshall, Boyne City, Clarence M. Williams, Alpena, and Earl V. McComb, Menominee; Twelfth district, Drs. Edward T. Abrams, Hancock, Henry E. Perry, Newberry, and Frederick M. Harkin, Marquette. The duties of these inspectors are to investigate, on advice from the state office, all outbreaks of communicable diseases, all matters pertaining to water-supply and sewage disposal, and to see that all local authorities attend to their duties in times of epidemic.

MINNESOTA

Personal.—Dr. George T. Baskett, assistant superintendent of the St. Peter State Hospital, was stabbed in the arm, May 8, by an insane patient who had improvized a dagger from heavy galvanized iron wire.——Dr. Leonard E. Claydon, Red Wing, has returned from abroad.

Medical Building Burns.—The two upper floors of the Medical Building, Minneapolis, including the offices of many physicians and dentists, were burned, May 5, with a loss estimated to be from $50,000 to $100,000. The fire is believed to have been of incendiary origin.

Iron Range Physicians to Organize.—At a meeting of the physicians of Mesaba Range held in Virginia, May 11, at the call of Dr. Charles B. Lenont, Virginia, Dr. John C. Farmer, McKinley, and others, it was agreed that an organization should be formed for the mutual benefit of physicians of that portion of Minnesota.

Railroad Water Supplies in Minnesota.—Following the promulgation by the Secretary of the Treasury of the regulation regarding water and ice furnished to passengers by common carriers in interstate traffic, the Minnesota State Board of Health undertook to examine the water supplies for passengers used by the railroads of that state, not only in interstate traffic, but in intrastate traffic as well. This examination was made by R. H. Mullon, H. A. Whittaker and B. M. Mohler of the Minnesota Board and a report made to the Surgeon General of the U. S. Public Health Service, whose aid and approval the Minnesota board had in prosecuting this work. It consisted of field and laboratory examinations and is summarized as follows: Over 50 per cent. (52.45 per cent.) of the supplies investigated could not be recommended in their present state as drinking water supplies. Of the 32 supplies on which recommendation was refused, 31 were pronounced unsafe by the field investigation and of these but 16 showed analytical evidence of pollution. In one instance only did the analytical results alone constitute the refusal for recommendation. A careful and adequate field investigation in addition to the analytical determinations is required before a satisfactory opinion should be ventured concerning the safety of a given water supply. The owners of practically all the condemned water supplies can convert these into safe supplies at a relatively small cost by following in detail the recommendations given each locality.

MISSOURI

Last Graduation from Ensworth.—On April 30, Ensworth Medical School, St. Joseph, graduated its last class and permanently closed its doors. This action is in accordance with the decision of a few years ago that the school would continue only until the class then enrolled had graduated. Nine students received degrees at the graduating exercises.

Personal.—Dr. Clarence B. Francisco, Kansas City, sailed for Europe, May 2.——Dr. Benjamin Y. Jaudon, Palmyra, has been appointed assistant medical director of the Missouri State Life Insurance Company, St. Louis, and will make his home in that city.——In a fire in the office of Dr. Arthur R. McComas, Sturgeon, April 15, his entire office equipment was destroyed.

New Officers.—Fourteenth District Medical Society at Marshall, April 23: president, Dr. Robert L. Evans, Boonville; secretary-treasurer, Dr. John R. Hall, Napton.——Southwestern Missouri Medical Society at Springfield, April 30 to May 1: president, Dr. Charles M. N. Rogers, Mansfield; secretary, Dr. Herbert S. Hill, Springfield, (reelected).——Fifth District Medical Association at Memphis, April 30: president, Dr. Byron B. Potter, Lancaster; secretary-treasurer, Dr. Edward E. Parish, Memphis.——Linton District Medical Society, May 5: president, Dr. Chambers B. Clapp; secretary, Dr. J. Curtis Lyter, both of Moberly.——Harrison County Medical Society at Bethany, May 1: president, Dr. Leslie R. Webb; secretary-treasurer, Dr. W. Worthington Vandivert, both of Bethany.

NEBRASKA

New Officers.—Dixon, Decatur, Cedar, Thurston and Wayne Counties Medical Society at Wakefield, April 27: president, Dr. Charles H. Maxwell, Dakota; secretary-treasurer, Dr. Buis Tender.

Personal.—Dr. A. J. Edstrom has succeeded Dr. C. B. Foltz as police surgeon of Omaha.——Dr. Elmer J. Updegraff, Omaha, who was operated on for disease of the stomach at the Methodist Hospital, May 2, is reported to be in a serious condition.——Dr. Charles F. Moon has been appointed house physician of the Douglas County Hospital, Omaha.

Impostor Faring Westward.—A physician of Lincoln warns physicians against a young man about 5 feet 4 inches tall, blond, blue eyes, who dresses neatly, speaks English fluently, and is aggressive, and who claims to be a medical student of the University of Heidelberg, but that through misfortune and the death of his father he has been obliged to discontinue his studies, and that he expects to enter a Chicago medical school this fall. He calls on professional men, and especially German physicians, telling hard-luck stories, and asking for assistance. He calls himself William Kahlkoff, but his right name is supposed to be L. Hofer. He has some knowledge of drugs, which he obtained by clerking in a German grocery. His name does not appear on the list of students of the University of Heidelberg. He has been heard from thus far in New York, Buffalo, Pittsburgh, Chicago, Milwaukee, Omaha, Kansas City and Lincoln.

NEW JERSEY

New Medical Institution.—A Philadelphia architect has prepared revised plans for a two-story brick municipal hospital for Millville, N. J., 32 x 100 feet, and to cost $20,000.

Contract for Sanatorium Awarded.—The contract for the construction of the new tuberculosis sanatorium pavilion for the Essex County Hospital at Cedar Grove has been awarded for $116,112. This is nearly $4,000 below the estimated cost.

Personal.—Dr. Arley I. Munson, Red Bank, has passed an examination for physician of a state institution, and will receive her appointment so that she may assume charge in the fall.——Dr. Samuel E. Weiner, Atlantic City, was shot at by a man said to be a paranoaic, April 27, but was not injured.

Alumni Meeting.—At the conclusion of the banquet July 1, which will close the annual meeting of the Medical Society of the State of New Jersey at Spring Lake, the New Jersey medical alumni of the University of Pennsylvania will hold their annual smoker. Dr. Alexander MacAlister is chairman, and Dr. Hyman I. Goldstein secretary of the committee on arrangements, both of Camden.

Campaign Against Mosquitoes.—Although Atlantic County can never be entirely free from the mosquito so long as conditions remain as they are in the Cape May County swamps, still with $26,000 to be spent in a campaign against the mosquitoes, this county will be greatly improved. Chief Inspector Eaton, who was for four years in the Canal Zone, will have the services of fourteen inspectors, five of whom will be engaged in a campaign against the fresh-water mosquitoes.

NEW YORK

Vaccinate State Hospital Patients.—Pursuant to orders of the Lunacy Commission, patients at the Hudson River State Hospital, numbering more than 3,000, have been vaccinated by the asylum staff.

A New Dispensary.—Plans have been filed with the Building Department for a four-story dispensary building to be erected at the north-east corner of Gouverneur Slip and Front Street. This will be known as the Gouverneur Dispensary and will be maintained by the city. The estimated cost is $200,000.

Protests Against Bronx Hospital Fail.—The protests of the residents of Seton Falls Park against the construction of a hospital for the treatment of contagious diseases has failed to move the Board of Estimate, which was authorized by the Comptroller to buy a site of 32 acres in the park at a price not to exceed $32,000.

Memorial for Dr. Le Fevre.—Mrs. Helen H. Le Fevre, the widow of the late dean of the New York University and Bellevue Medical College, Dr. Egbert Le Fevre, has made a donation of $10,000, the income of which is to be applied toward the salary of the person who from time to time may accept the office of dean of the Medical College of the University. The trust is to be known as the Dr. Egbert Le Fevre Deanship Fund.

Centenary of Edward Mott Moore.—The Committee of One Hundred of Rochester, appointed to arrange a fitting celebration of the 100th anniversary of the birth of Dr. Edward Mott Moore, and to erect a monument to his memory, has arranged that the celebration shall be held on July 15. The park board has contributed $2,000 toward the expenses of the celebration, and the committee has adopted resolutions asking the city to erect a life-size statue of Dr. Moore, to be placed in Genesee Valley Park.

Civil Prosecutions by Health Department.—Heretofore violations of the Sanitary Code or of the rules and regulations of the Health Department have been prosecuted for criminal action in such violations, but now the department has determined to prosecute such cases as civil actions, since it is frequently difficult to establish criminal intent in such violations. Five such cases have already been terminated and in each instance a judgment for $50 and costs has been obtained. This procedure was inaugurated in connection with the work of the Bureau of Food Inspection.

Asks Aid for Defectives.—An attempt is being made by the State Charities Aid Association and the Association for Improving the Condition of the Poor to induce the legislature at its special session to appropriate $500,000 for additional beds at Letchworth Village, Craig Colony, and Rome. Each legislator has been sent a list of 1,000 feeble-minded persons who experts believe should be cared for by an institution, and the Clearing House for Defectives in New York City has on file 3,000 additional names of persons who need institutional care. If no appropriation is made, it is probable that a bond issue will be authorized.

Friedmann's Tuberculosis Treatment in City Hospitals.—Requests for information in regard to the results of the Friedmann tuberculosis treatment have led the Department of Health to ascertain the recent status of seventy-seven cases treated at the time of Dr. Friedmann's visit to this city. Of the seventy-seven patients treated, nineteen could not be found, while eleven were reported to have moved out of town permanently. The department was therefore able to obtain reports on but forty-seven of the cases in question. These reports show that there are at present five of these patients at home; twenty-two are in hospitals or sanatoria (indicating failure to cure); seven are attending clinics (showing the need of further treatment); one is attended by a private physician, and twelve have died.

Bad Food at State Hospitals.—Inspectors of the Department of Efficiency and Economy together with experts from the Bureau of Animal Industry of the United States Department of Agriculture have completed an inspection of the fourteen state hospitals and made their report to the state hospital commission. This report describes unbelivable conditions in nearly all of the state institutions. According to the report the Hudson River State Hospital at Poughkeepsie has been using the milk from a herd of tuberculous cattle for the past eighteen months. Large quantities of meat and eggs were ordered destroyed at several of the other hospitals. It is stated that at the Utica State Hospital the sanitary condition of the bakery was intolerable and a menace to both patients and employes. In the Willard State Hospital 3,200 pounds of pork was found spoiling for lack of care. It is stated further that the state is losing from $30,000 to $35,000 annually because of the loose construction of the law regarding the maintenance of the families of the employees.

Health Matters and the Chamber of Commerce.—The Rochester Chamber of Commerce, in addition to the attention given to the welfare of Rochester in commercial affairs, has a Public Health Committee to look after health and sanitary matters, which is one of the most valuable divisions of the body. The *Official Bulletin* for May 15 says that the Chamber of Commerce has appointed a physician to examine all its employees with reference to their general health and the presence of transmissible diseases which might be spread among themselves or those with whom they come in contact. It also approves and encourages the plan now adopted by many employers of having their employees examined and followed up by regular inspections. Among the other health and welfare subjects mentioned in the *Bulletin* are the matter of smoke-prevention, clean-up week, the prevention of street accidents and legislation concerning the restriction of the employment of women and children in mercantile establishments. The Chamber in this way proves a valuable ally to the health department in improving health conditions in the city.

New York City

Typhoid and Vacationists.—The weekly *Bulletin of the New York Board of Health* warns persons who take vacations this summer of the danger of contracting typhoid fever, and urges them to be vaccinated against the disease. Antityphoid vaccine can be obtained without charge from the Department of Health. The product is prepared after the formula of the vaccine used in the United States Army.

Facilitating the Distribution of Health Information.—The health department has arranged with two of the large industrial insurance companies of the cities to distribute through their agents and collectors public health bulletins, circulars and health literature of all sorts. Three thousand agents visit the homes of 750,000 families weekly. A new brief folder giving information about typhoid fever and its prevention, printed in a number of different languages, is being prepared for distribution by this means.

Trade School for Cardiac Convalescents.—A report has just been made on an experiment undertaken last year in the care of cardiac convalescent's. A home was opened at Sharon, Conn, where patients from the wards and dispensaries of New York hospitals receive care and treatment for several months and at the same time are taught a trade in which they can engage without danger to their crippled hearts. Provision is also being made to provide employment for the patients when their term of treatment in the home is completed. Among the directors of the organization are Drs. John Winters Brannan, Frederick Brush, Hubert V. Guile, John H. Huddleston and Warren Coleman.

NORTH CAROLINA

Tribute to McBrayer.—The Asheville Board of Health pays Dr. L. B. McBrayer, who recently resigned to accept the medical directorship of the State Sanatorium for Tuberculosis, at Montrose, N. C., a fine tribute by devoting the whole of the May issue of its monthly public health bulletin to an account of the banquet tendered Dr. McBrayer last month when leaving Asheville for the taking up of his new duties. The issue contains his portrait and a detailed account of the speeches at the banquet with Dr. McBrayer's response.

Meetings to Come.—The Medical Society of the State of North Carolina meets for its sixty-first annual session, in Raleigh, June 16, under the presidency of Dr. J. M. Parrott, Kinston, N. C.——The North Carolina State Health Officers' Association will hold its annual meeting June 15, 1914.——The annual joint session of the State Medical Society and the State Board of Health will be held June 17. The session of the Board of Examiners will probably conclude on the second day of the State Society's.——This grouping of meetings of state organizations should be most helpful and interesting to all. It also tends to conserve and further develop the cause of medical solidarity and further unite the various medical bodies of the state. This holding of the various medical meetings at the same time and place is rather a peculiar North Carolina custom originating in 1859, the year the State Board of Medical Examiners held its first meeting, and as the needs of the profession and people have developed the other allied societies and boards, they naturally follow the established precedent of meeting at the same time and place with the parent organization, the State Medical Society. Besides conserving and holding most closely together the different professional bodies. the custom is a great time-saver to the busy physician in that he is enabled to take part in the various meetings, thus keeping in close touch with all the organized professional interests of his state; with the minimum expenditure of time and expense.

OHIO

Dinner to Women Physicians.—The Women's Medical Club of Columbus gave a dinner, May 3, in honor of women physicians attending the Ohio State Medical Association.

Personal.—Dr. Johann F. Dolina has succeeded Dr. Henry D. Rienhart as laryngologist and rhinologist on the medical staff of the Miami Valley Hospital, Dayton.——Dr. George Goodhue, Dayton, is reported to be seriously ill at his home.——Dr. Esmond A. Childs, Geneva, who was operated on for appendicitis at Cleveland recently, has returned home convalescent.——Dr. John H. Axline, Lancaster, suffered a slight cerebral hemorrhage at the Zanesville Hospital, May 6.——Dr. William M. Calhoun has resigned as president of the training school of the East Liverpool City Hospital.

PENNSYLVANIA

Gift to Abington Hospital.—On May 15, the new Abington Memorial Hospital was open to public inspection, and the Board of Trustees announced a gift of $250,000 to the endowment fund, by George W. Elkins of Elkins Park. The gift is in memory of his wife, Stella McIntire Elkins. Mr. Elkins had already given $100,000 in memory of his wife. The hospital will start a training school for nurses immediately. The new buildings, located at York and Woodland Roads, were used for hospital purposes May 18.

Philadelphia

Baby Saving Show.—The Baby Saving Show of the Child Federation in the City Hall Court Yard, was officially opened by Mayor Blankenburg, May 12. Exhibits of proper food, clothing, toys, bottles, tubs, towels and numerous things used for babies, were shown in small booths. The exhibit designed as a preventive, not a curative, measure will be open to the public every day, except Sunday, from 9 a. m. to 5 p. m., until October 1.

Personals.—The Elliott Cresson Gold Medal of the Franklin Institute was presented to Provost Edgar Fahs Smith of the University of Pennsylvania, May 20, in recognition of his work in the field of Electro Chemistry, and in view of his many contributions to the literature of chemical science. Dr. Harry F. Keller, head of the Department of Science, made the presentation address, and the medal was presented by Dr. Walton Clark, President of the Institute.——Ex-Surgeon General Charles F. Stokes, U. S. N., was a guest of honor of the West Branch of the Philadelphia County Medical Society, at its "social night," May 18.

City Milk to be Pasteurized.—Following a meeting of the Board of Health, May 11, Chief Vogelson, of the Bureau of Health, announced that the new regulations regarding the pasteurization of milk will go into effect July 1. Under these rules all milk from non-certified dairies must be pasteurized. A vigorous campaign against compulsory pasteurization of milk was planned by the members of the Independent Milk Dealers' Association, at a mass meeting held on the plaza of City Hall, May 15. This meeting was a direct protest against the recent order from the Board of Health. More than 2,000 persons were present and resolutions were adopted to the effect that the pasteurization of fresh milk was detrimental to the value of the product.

VIRGINIA

Donation to Hospital.—Rockingham Memorial Hospital, Harrisonburg, has been presented by Mr. R. G. Alexander of New York with an elevator, the installation of which cost $1,000.

Raises Milk Standard of Richmond.—Dr. E. C. Levy, health officer of Richmond, announces that the City Board of Health has passed an ordinance, effective September 1, which requires that all milk and cream in the Richmond markets shall be obtained from cows that have passed the tuberculin test.

Personal.—Dr. Julian F. Ward has been elected mayor of Winchester.——Dr. George Ben Johnston, Richmond, has been appointed a member of the Board of Visitors of the Medical College of Virginia, the commission to last for life. This appointment renders it necessary that Dr. Johnston resign from the faculty of the college.——Dr. Herbert Old, Norfolk, has been appointed assistant medical director of the Provident Life and Trust Company, Philadelphia, with headquarters at Philadelphia.

GENERAL

American Pediatric Society.—This society will hold its twenty-sixth annual meeting at Stockbridge, Mass., May 26-28. The preliminary program includes addresses on almost every phase of the diseases of children and their care.

Central Railway Surgeons Hold Meeting.—The annual meeting of the Central of Georgia Railway Surgeons' Association met in Savannah, May 5 and 6, and elected the following officers: president, Dr. Henry B. Disharoon, Roanoke, Ala.; vice-president, Dr. William C. Howell, Dothan, Ala.; and secretary-treasurer, Dr. Walter E. Saunders, Arlington, Ga.

Medical Jurisprudence Association Elects.—The second annual meeting of the American Association of Medical Jurisprudence was held in New York City, May 2. The following officers were elected: president, Charles A. Boston; vice-presidents, Oscar W. Ehrhorn and Dr. D. Percy Hickling, Washington, D. C.; secretary, Charles P. Blaney, and treasurer, John C. West.

Meeting of the American Medico-Psychological Association.—The seventieth annual meeting of the American Medico-Psychological Association will be held in Baltimore May 26 to 29, inclusive. A symposium on "Paresis" will be held May 26. On the second day the annual address will be delivered by Dr. Lewellys F. Barker on "The Relation of Internal Medicine to Psychiatry," and on the fourth day there will be a symposium on "Eugenics."

To Study Tropical Diseases.—The foundation stone of the new School of Tropical Medicine at Calcutta, for the site and laboratory of which the government of India has appropriated $195,000, was laid recently by the governor of Bengal. The institute will accept students from all over the world, and it is hoped that students of medical research institutions of the United States may be sent to the school for study. Communications regarding the school should be addressed to Lieut.-Col. Leonard Rogers, I. M. S., Medical School, Calcutta.

Bequests and Donations.—The following bequests and donations have recently been announced:

Kings Daughters' Hospital, Shelbyville, Ky., donations of $4,000 for an additional building.

Jewish Hospital, Philadelphia, a donation of $5,000 for a perpetual free bed, in memory of the family of Joseph and Amelia Nevil, by George Nevil.

Medical School of the University of Cincinnati, an endowment fund of $31,500, from the estate of Frances Gibson; $1,000 annually for the establishment of six medical school scolarships, a gift from Julius Fleischmann.

American Physicians' Association Meets.—At the closing session of the Association of American Physicians, held at Atlantic City, May 13, the following officers were elected: president, Dr. Samuel J. Meltzer of the Rockefeller Institute, New York; vice-president, Dr. Henry Sewall, Denver; secretary, Dr. George M. Kober, Washington, D. C.; recorder, Dr. Thomas McCrae, Philadelphia; treasurer, Dr. J. P. Crozer Griffith, Philadelphia, and representative on Executive Committee of the Congress of American Physicians and Surgeons, Dr. Theodore C. Janeway, Brooklyn.

American Dermatological Society.—At its annual session held in Chicago, May 14-16, the American Dermatological Society adopted resolutions to the effect that a memorial be presented to the President of the United States and Congress, setting forth the dangers of the leper at large and urging detention in a place under national control. A permanent committee on leprosy was appointed, consisting of Drs. Martin F. Engman, St. Louis, chairman; Charles J. White, Boston, and Dr. James McFarlane Winfield, Brooklyn. The following officers were elected: president: Dr. Sigmund Pollitzer, New York City; vice-president, Dr. Martin F. Engman, St. Louis; and secretary and treasurer, Dr. Oliver S. Ormsby, Chicago.

Appropriations for National Children's Bureau.—The Committee of the House of Representatives in acting on the appropriation of $164,000 asked for by Miss Julia C. Lathrop, head of the National Children's Bureau, reduced the amount to $25,000, but the House raised this to the original sum asked. The Senate has now confirmed this and the Bureau will get the full appropriation. Concerning this the Chicago *Tribune* says:

> If any expenditure is justified from the point of view of constructive statecraft it is an expenditure which conserves the sources of citizenship. Sound manhood and sound womanhood make a state, and these no state can have unless it protects the soundness of childhood in body and mind.

Hearing on the Palmer-Owen Bill.—Friday, May 23, the third public hearing was held on the Palmer-Owen bill, which forbids the shipment in interstate commerce of goods produced in establishments not conforming to the age requirements of the bill in the employment of child labor. Among the many organizations supporting the bill are the Child Labor Committee of Virginia, the Executive Council of the Massachusetts Board of Trade, and the Los Angeles Chamber of Commerce. According to the National Child Labor Committee, of 78,000,000 people who live in mining states, 41,000,000 have forbidden children under 16 to work in mines; 45,000,000 have placed on the statute books of their states an eight-hour day for children, 58,000,000 people have prohibited night work for children under 16.

Tropical and Parasitic Diseases Among Immigrants.—Surgeon-General Blue (*Pub. Health Rep.*, May 15) directs medical officers of the Public Health Service engaged in the medical examination of aliens to give especial attention to the detection of the following diseases:

Kala-azar. Reported in China, Egypt, Arabia, Tunis, Algiers, Greece, Malta, and generally in the region surrounding the Mediterranean Sea.

Schistosoma Haematobium. Blood fluke infection. Found in South Africa, Egypt and Cuba.

A group of infections found especially in China and Japan as follows: *Clonorchis.* Formerly *Opisthorchis sinensis,* also called Japanese liver fluke. It is stated to be as common in some parts of Japan as hookworm is in Africa. *Paragonimus Westermanii.* Japanese and Chinese lung fluke. The disease caused by this parasite is extremely chronic and is accompanied by more or less serious hemorrhage and is often mistaken for consumption. *Diplogonoporus Grandis.* Japanese tapeworm. Resembles Russian tapeworm. *Schistosoma Japonicum.* Blood flukes of China and Japan.

Guiteras Called to Tampico.—It has been announced that Dr. G. M. Guiteras of the Public Health Service has been called to Tampico, Mexico, with the consent of the constitutionalist forces, now in control of that place, to "clean up" the city. Tampico is believed to be a breeding ground for many tropical conditions, especially yellow fever, small-pox and malaria. Dr. Guiteras will investigate the sanitary situation fully and make recommendations to remedy the many evils he will no doubt discover. His absence from Vera Cruz will place in charge of health conditions there Dr. Von Ezdorf, the next officer in charge under the temporary United States control. This movement on the part of the constitutionalists is significant of the power for good which the United States possesses in its public health service, and shows again the recognition now being accorded to these workers by foreign nations.

Dr. Theobald Smith Becomes Director of New Institute.—Announcement has been made by the Rockefeller Institute for Medical Research that Dr. Theobald Smith, now professor of comparative pathology in the Harvard Medical School, has accepted the position of director of its new department of animal pathology. This department has but recently been established, and the fact that Mr. Rockefeller has added $1,000,000 to the endowment of the institute for the support of this department, and that Mr. James J. Hill has pledged $50,000 for its use in the study of hog cholera became known only a few weeks ago. The department is not yet organized or equipped, but it is expected to begin active work within a year. In the meantime, Professor Smith will continue his connection with Harvard University so long as may be necessary to complete work on which he is now engaged at its medical school. He has had a distinguished career as a pathologist and bacteriologist and is considered as one of the world's foremost bacteriologists.

Safety Campaign Lessens Personal Injury Cases.—During the last four years the leading industries of the country have paid a great deal of attention to the question of safety to the end that the number of personal injury cases might be lessened. Since the movement was started, the Chicago & Northwestern Railway has reduced the number of accidents nearly 30 per cent. During the four years 10,000 fewer persons were injured on this system than in the preceding four years. On the Great Lakes the Lake Carriers' Association has conducted a systematic campaign for the elimination of the avoidable accident by distinctly marking dangerous places and by appointing safety committees from among the crew on each ship. In addition, the association has begun a campaign on sanitation to promote the physical well-being of the men. The initial steps in the campaign have to do with the care and preparation of food supplies. Every dealer on the whole chain of lakes supplying meats, milk, groceries and ice to the boats has received a circular from the Welfare Plan Committee of the Lake Carriers' Association outlining certain simple rules to be observed in the care of foodstuffs. In addition, the sanitary committee of the Lake Carriers' Association has defined the areas on the Great Lakes from which drinking water may be drawn for the vessels.

CANADA

Typhoid Abated.—The outbreak of typhoid fever in the province of Quebec along the Richelieu River has abated. The water-supply of numerous towns is being treated with hypochlorite.

Adami Gold Medalist.—John George Adami, professor of pathology at McGill University, Montreal, has been awarded the Fothergill gold medal by the Medical Society of London, England, for 1914, for his work on pathology and its application to practical medicine and surgery.

Medical Act Amended.—The New Brunswick Medical Act has been amended. The matriculation fee has been advanced from $5 to $10; examination in medicine from $10 to $30; registration from $10 to $40. Registered physicians are now required to pay an annual fee of $1, or a single life payment of $20.

Vaccination at McGill.—The Corporation of McGill University at Montreal has adopted a regulation that all students entering the university shall be required to present a certificate or other satisfactory evidence of successful vaccination, or at once be vaccinated in a manner satisfactory to the medical examiner.

Tuberculosis Experts to Meet.—The fourteenth annual meeting of the Canadian Association for the Prevention of Tuberculosis, of which the governor-general is honorary president, will be held in Halifax, N. S., July 13 and 14. Dr. S. Adolphus Knopf, New York City, will deliver the oration on "The Modern Warfare Against Tuberculosis as a Disease of the Masses."

Personals.—Dr. Max O. Klotz, President of the Ontario College of Physicians and Surgeons, has sailed for Europe.——Dr. J. Price Brown, a well-known rhinologist and laryngologist of Toronto, has been forced to retire from active practice on account of glaucoma.——Dr. Charles F. Martin, Montreal, has returned from a trip round the world.——Dr. Francis R. Gow, Halifax, N. S., has been appointed chief medical officer and inspector for immigration at that port.

University News.—The annual instruction for the benefit of postgraduate students conducted by the medical faculty of McGill University, Montreal, will commence June 1.——Lectures in the medical department of McGill University ceased April 30. The examinations will be held May 4 and succeeding days. The graduating class this year numbers seventy-five.——Examiners at Toronto University will take part this year at the examinations of McGill University, while those from McGill will go to Toronto. This will be done this year only in anatomy and pathology, but in future years this is expected to be extended to embrace many subjects.

Hospital News.—The municipal grant to the Prince Rupert (B. C.) Hospital has been reduced from $10,000 to $7,000. The British Columbia government has made a grant of $100,000 to the Vancouver General Hospital; next year the amount will be $125,000.——A grant of $2,000 has been made by the provincial government of British Columbia for a new hospital at Masset.——The Medicine Hat General Hospital has received a municipal grant of $19,000. Of this amount, $5,000 will be devoted to current expenses and $14,000 for property purchase.——A sanatorium for the treatment of tuberculosis cases is to be built at once at Calgary. A year ago the sum of $30,000 was voted by the Calgary Council for the purpose.——The Brandon (Man.) Hospital is to expend $100,000 on a maternity home and extend the mission building and nurses' home.——In the province of Ontario there are eighty-nine public hospitals, fifty-seven private hospitals, thirty-seven refuges, eight sanatoria for consumptives, thirty-three orphanages, three homes for incurables and thirty-one county houses of refuge. During the year ended Sept. 30, 1913, 68,738 patients received treatment in the hospitals, and 4,058 deaths occurred. The total amount expended during the year on hospitals was $3,155,340, of which amount the Ontario government granted $232,276.

LONDON LETTER

London, May 8, 1914.

The Royal Commission on Venereal Diseases

The Society of Medical Officers of Health has called the attention of the commission to the lack of exact information regarding the present prevalence of syphilis and other venereal diseases either as causing illness or death; the *misleading or incomplete character* of certified causes of death, particularly of the remote causes in fatal diseases of the nervous or circulatory systems; the absence of any systematic provision for the recognition of the diseases in question, and the relation of syphilis to miscarriage, stillbirths and deaths among infants in the first year of life, especially the first four weeks.

Sir Victor Horsley insisted on the importance of education of the public in regard to venereal diseases and of children in sex matters. If the nature study part of elementary education were extended and every child taught the groundwork of hygiene, instruction in sex matters could gradually be brought into its mind. In secondary schools full instruction could be given. Sir Victor dwelt with the difficulty with which physicians are faced in public health matters by reason of the law of libel. They ought to be able to warn any one who, to their knowledge was likely to be infected, but at present they were liable to an action for libel. He was in favor of notification to the health officer. This would probably be resented both by physicians and by the public, but the history of notification showed that objections had been made in regard to even the simplest diseases. The notification of scarlet fever was violently resisted at first. The notification should be confidential. He was in favor of treatment in special wards of general hospitals.

Suggested Prohibition of Marriage of Neurotics

In a lecture at the Institute of Hygiene, a leading neurologist, Dr. J. S. Risien Russell, spoke of the congenital defects of the brain and consequent idiocy that tend to follow intermarriage, while to the mating of neurotics, especially epileptics, he said, could be traced a large proportion of neuroses. The rather remarkable fact that neurotics actually tend to marry neurotics called from him the expression, "Would that neurotics could be attracted by the phlegmatic, as the offspring would be much less likely to be productive of so many unstable individuals prone to various mental and nervous disorders." On the facts, however, most authorities are in agreement. The question of prevention is the difficulty. Dr. Russell advocated the full policy of prohibition of marriage of persons "known to be affected by some malady of the nervous system that is hereditarily transmissible, even when it is proposed that they should mate with some one of strong nervous organization who comes of a stock free from any suspicion of nerve degeneracy." Neurotic parents should be made to recognize the *importance* of having their children brought up away from the neurotic atmosphere in which they are usually steeped and which cannot fail to be productive of the most harmful effect.

The Struggle Between the Profession and Friendly Societies in Australia

The relations between the profession and the friendly societies at the antipodes are of the same strained nature as in this country. At a conference of friendly societies held in Sydney considerable discussion took place on this subject. A paper read by Mr. Robert Clark of South Australia shows very well the friendly societies' point of view. The antipathy of the profession in this country to "medical institutes" (organizations for the employment of whole-time physicians to attend the members) has been described in a previous letter to The Journal. In Australia there is the same antipathy. Mr. Clark said that through the establishment of medical institutes, many members of the profession had ceased to entertain that friendly feeling toward societies that formerly contributed to the welfare of all concerned. The institutes, as agencies in friendly society work, had proved of considerable value in some localities, but, owing to the hostile attitude of the British Medical Association, the choice of medical officers was now practically confined to what might be termed "non-union" doctors, and it seemed probable that in the near future the institutes would have trouble in procuring the necessary professional assistance. The friendly society practice had assisted a large number of physicians to attain eminence in the profession. The extent of benefits to members' wives and families had been extremely irritating to the profession, but lack of organization and keenness of competition had enabled the societies to make far-reaching contracts. Clark denied that the societies had sweated the profession. Invariably the doctor had quoted the terms which the society had accepted. That the societies had had the best of the bargain during recent years was generally admitted by leading representatives, and that the profession earned and deserved higher rates of remuneration was freely acknowledged at the 1912 Sydney conference, which agreed, without demur, to increased rates. The organization of the medical profession during the past eight or ten years had been truly marvelous. It was asserted that 98 per cent. of the profession were in the British Medical Association. They were in a position to dictate terms, and it was improbable that societies would be able to supply in the near future the existing medical benefits. The public hospitals were practically closed to lodge members, largely through the influence exerted by the profession. Until very recently a member was admitted *on order*, and, if he was in a position to pay for attention, he was called on to do so. No objection could be urged to this, and the amount was usually fixed at $5 per week. Now only the indigent were eligible for prolonged treatment. The lodge and family doctor was disappearing, and the mutual confidence which, true to the *traditions* of each side, existed for generations, was rapidly being dissolved in the commercial atmosphere of the present.

PARIS LETTER

Paris, May 1, 1914.

The Prophylaxis of Leprosy

At its session, April 28, the Académie de médecine terminated the open discussion on the action of the Minister of the Interior (The Journal, Feb. 28, 1914, p. 711) on leprosy, its dangers, and the preventive measures which should be taken *against it. The members of the academy passed the* following resolutions: (1) leprosy should be included among reportable diseases; (2) lepers should be submitted either to oversight or to isolation, as the case may demand; (3) foreigners suffering from leprosy should be excluded from French territory; (4) a special commission should consider each case. Furthermore, the academy emphasized the fact that to work for the prevention of leprosy in France would be useless unless the public officials could be impressed with the need of rigorous measures against the diffusion of leprosy in the colonies and the countries under the French protectorate, in which the danger is far greater than in the metropolis.

Death of Professor Van Tieghem

French science has suffered a great loss in the recent death of the famous botanist, M. Philippe Van Tieghem who recently died, aged 75. He had been a member of the Académie des Sciences for about forty years and was one of the first of Pasteur's collaborators. At that time he prepared for his doctor's degree in physical sciences, his thesis on the subject of ammoniacal fermentations, which is still considered authoritative. It was in botany, however, that his influence was most important; his "Traité de botanique" completely altered the method of studying that science, at home as well as abroad. The classification of plants has been, one might say, revolutionized by the works of Van Tieghem.

Peritoneal Tuberculosis in Infants

At the last session of the Académie de médecine, Dr. Marfan, professor of therapeutics at the Faculté de médecine de Paris, gave an interesting address on this subject. Tuberculous peritonitis is observed most frequently in advanced childhood, from 6 to 15 years of age; below the age of 6 it is infrequent and appears less often in early infancy. Before the age of 2 years the disease is rarely seen, and has clinical aspects quite unlike the usual symptoms, so that its diagnosis is ordinarily very difficult. Without doubt, some ascitic and fibrocaseous conditions may be observed in infants as well as in older subjects. More often ascites and "peritoneal nodules" are absent; the clinical picture lacks clearness; the diagnosis long remains uncertain. Tuberculous peritonitis is much more dangerous in infants than in older children; below the age of one year it seems invariably to result in death. Its progress is also rapid; instead of lasting for years, the disease develops in some months or even in weeks. One of the conditions which renders the prognosis more grave is the difficulty of recognizing the disease in time; to recognize it sooner would, perhaps, mean its more successful treatment. Without doubt the skin reaction to tuberculin has greatly favored the early recognition of the disease. In spite of the great value of this test, however, the evidence which it furnishes is not sufficient to establish a diagnosis in every case; when the test is positive it indicates that there is a tuberculous lesion in the organism, but it does not show the location nor does it tell us whether the lesion is active or dormant. For these reasons the clinical examination retains its value.

For guidance in diagnosis, Marfan attaches great importance to the diverse forms of "protuberant abdomen" in the infant. Beside the swelling due to ascites, or to a liquid or solid tumor, two varieties of enlarged abdomen remain: the flaccid, and the tympanitic. The flaccid variety is due to relaxation of the gastric, intestinal and abdominal muscles, and almost always accompanies rachitis, of which it is one of the elements. The tympanitic enlarged abdomen has a varying significance according to its transitory, intermittent, or chronic nature. Transitory tympanites is caused by acute gastro-enteritis or acute peritonitis; intermittent tympanites, whether slight or general, is caused by nervous affections of the stomach or intestines, and perhaps results from the production of gas. As for chronic generalized tympanites, its significance varies according to whether or not it is accompanied by digestive disturbances with diarrhea or constipation. Chronic tympanites with chronic diarrhea is due to intestinal ulcerations; with obstinate constipation and dating from birth or very early life, it is indicative of those forms of congenital constipation which are related to intestinal malformation, and are still grouped under the name of Hirschsprung's disease; without diarrhea and without obstinate constipation, it appears to result from tuberculosis either of the peritoneum, or of the mesenteric ganglions in which the intestine is not involved.

BERLIN LETTER

Berlin, April 24, 1914.

Annual Meeting of the German Surgical Society

The most important subject for discussion at the meeting of the Deutsche Gesellschaft für Chirurgie, which was held as usual at Berlin, in the middle of April, was the cause and treatment of postoperative ventral hernia, the discussion of which was introduced by Sprengel of Brunswick.

POSTOPERATIVE VENTRAL HERNIA

The speaker distinguished, in addition to the hernia of the abdominal wall in its proper sense, paralysis of the abdominal wall (following section of the nerves supplying the rectus), and stretching of the abdominal wall. The causes of these conditions are the tamponade, wound infection, inaccurate suture and improper suture material and serious postoperative injury, as from vomiting, etc. To these four factors, which have been long known, may be added a fifth, which has been brought out by recent investigation, namely, the use of a physiologically incorrect method of abdominal incision. In view of the fact that not only the technic of tamponing but also the indication for its application have been modified in the course of time and that, on the other hand, a more correct plan of incision is possible, the speaker recommended the following: When it is possible, an alternate incision is to be used, such as is applicable for most gynecologic laparotomies, in almost all appendix operations, in most operations on the kidneys and finally for the treatment of all intraperitoneal and retroperitoneal abscesses. For all severe cases, that is, in general, cases in which a simple suture by layers is not sufficient with a physiologically correct incision, Sprengel recommends the mattress-suture with catgut and a fine linen thread superposed (the material in suppurative cases should be boiled catgut, otherwise fine linen).

Drainage and tamponade he regards as supplementary to the discharge from the abdomen obtained by the operation. By limiting these and fixing more exactly the indications, the prognosis of cases treated by tampons has been improved, although the number of cases has become greater. The method of incision appears not to have the same importance for cases treated with tampons, at least in the upper part of the abdomen, as for the cases which are sutured immediately and the abdomen completely closed. It may be shown by statistics that in the upper part of the abdomen, hernia formation is less frequent than in the lower part, probably because the demands on the abdominal wall are less. The important question, whether or not the attempt to limit the use of tampons also involves danger, was answered in the affirmative and thoroughly discussed. The indication requiring a secondary operation to close the abdomen from fear of a postoperative hernia, the speaker could not endorse. The operative measures for the treatment of an extensive ventral hernia were discussed on the basis of whether the muscular and fascial tissue present (1) is sufficient for a satisfactory closure, or (2) is not sufficient for a satisfactory closure, or (3) is quite insufficient. The speaker advocated an extensive application of transplantation of fascia and condemned the use of material foreign to the body. The autoplastic use of muscle in the sense of the bridge plastic method of Pfannstiel-Menge should be considered as a last resort in extensive hernia. A modification of the last method was recommended.

In the discussion, Perthes of Tübingen recommended the overlapping method of Mayo not only for operations on hernias which have already occurred, but also to prevent them. He had observed only two hernias as a result of infection among thirty-nine cases in which operation had been performed by this method.

Völcker of Heidelberg laid great stress on the preparation of patients who are to be operated on for hernia (reduction of obesity, massage). In the operation itself, he tries to avoid, as much as possible, the opening of the hernia.

Menge of Heidelberg emphasized the fact that the musculature plays a much more important rôle in preventing hernia than the fascia and the aponeuroses. It must be well sutured and anchored by means of a cross-suture of the fascia. In sixty cases which were examined after the operation, he found no hernia. He opposes the wearing of a bandage after the operation.

König of Marburg emphasizes the importance of gymnastic exercises of the abdominal muscles and believes that the earlier demands made on these muscles in children, in whose cases drainage is more frequently employed than in those of adults, protects them from hernia. He employs periosteum from the tibia in cases in which he can get a piece wide enough; in other cases he uses fascia.

Wullstein of Bochum laid stress on the importance not only of the muscles but also of every single layer of the abdominal wall. He uses the principle of doubling in all the layers. He has never found it necessary to use foreign material. He does not agree with Sprengel that a prophylactic operation is not indicated. In case of large incisions and corpulent persons, Wullstein regards this as indicated. In order to obtain a good result, the pendulous abdomen, which is usually present, should be corrected.

Küttner of Breslau, in contrast to the plan of Sprengel, has always sutured with silk and moistened the line of suture with 0.1 per cent. mercuric chlorid, refraining from running sutures. He has remained faithful to the longitudinal incision.

TREATMENT OF MALIGNANT TUMORS

The reports of von Eiselsberg of Vienna on his experience in the treatment of malignant tumors with radium and the Roentgen rays also excited an extensive debate. The speaker first considered the radium treatment and distinguished the prophylactic and the curative treatment. In the first class he has seen good effect in a number of cases, especially a case of carcinoma of the upper jaw (in which operation was performed in 1910) but, on the other hand, he also had injurious effects, as in one case of carcinoma of the tongue. With a view to cure, he has treated only inoperable cases and has seen healing in a number of cases in which, however, a sufficient time has not elapsed to permit him to speak of a permanent cure. Cases of basal-celled carcinoma have shown especially favorable results (seven cures in nine cases). In some cases, by the rays he was able to make operable tumors which were otherwise apparently inoperable. A malignant tumor of the thyroid was healed, but the patient acquired a large radium ulcer which made a plastic operation necessary. Eiselsberg lays stress on the fact that in such cases one must accept this accident as a lesser evil. In a large number of cases, only temporary improvement was obtained. In four cases of carcinoma of the esophagus with much stenosis, dilatation occurred very quickly; but in some of these a new stenosis developed above the tumor as a result of radium burns. Aside from these lesions, however, cases were observed in which the treatment had a directly unfavorable effect. When healthy vessels traverse the area irradiated, there is a direct danger of erosion and consequent hemorrhage. In some cases, also, a rapidly increasing cachexia was observed as a result of the absorption of the tumor material destroyed by the radium. The same is true of the Roentgen rays as of radium. As yet there have been no permanent successes, but remarkable improvement has resulted. Here also, one must not be deterred by burns of the skin if there can be obtained thereby a cure of the patient from his malignant disease. From his experience, Eiselsberg would give the preference to radium in carcinoma of the esophagus and rectum, but, on the other hand, in a large part of other cases, he prefers the Roentgen rays. Operation should still be performed in operable cases; inoperable cases should receive radiotherapy, and prophylactic irradiation should be undertaken.

In the discussion, Wilms of Heidelberg emphasized the importance of prophylactic irradiation, especially for carcinoma of the breast. In twenty cases of carcinoma of the breast which he irradiated after the operation, the patients suffered no relapse. He was inclined to believe that one might be content with extirpation of the tumor in carcinoma of the breast if an energetic postoperative treatment with the rays was carried out. The regional lymph-nodes were particularly influenced. He explains this by the fact that the autolytic processes which are going on ordinarily in the glands are increased still more by the action of the rays. Carcinomas of the lips and tongue are especially suited to radiotherapy.

Spalitzer of Vienna made a special report on cases treated with the Roentgen rays at the Vienna clinic. Of sixty-four cases, twelve were healed, seventeen remarkably and thirteen slightly improved. Five were aggravated and seventeen showed no effect. These results can be obtained only with modern apparatus by using thoroughly filtered high doses and hard tubes. In the previous use of radium an ulcer occurred more readily. Operable tumors belong to the knife.

Tilmann of Cologne emphasized the slight penetration into carcinomatous tissue and the variable effect of the rays on various tumors which for the present make radiotherapy so uncertain that operable tumors should not be submitted to it. On the other hand, Krönig of Freiburg, in view of the unfavorable statistics of operation, would have operable tumors treated with the rays and that not only in case of carcinoma of the female generative organs but also carcinoma of the breast. Müller of Rostock protested against this proposition, saying that we do not know whether we can secure a final cure of carcinoma with the rays (that is, over five years). On the other hand, we do know that this is attained by surgery.

Werner of Heidelberg also had permanent cures to report; 286 cases were treated with mesothorium. Of thirty-seven carcinomas of the stomach, a distinct retrogression was observed in eight cases. Of nineteen cases of cancer of the esophagus, ten were maintained in good condition for six months, but only one longer than a year.

Heymann of Breslau reported that in the gynecologic clinic of that place operable tumors were surgically treated, but a preliminary treatment with the rays was undertaken for the removal of fetor and hemorrhage. The prophylactic postoperative treatment had been successful, but it must be carried on energetically for many months. The combination of the Roentgen rays with mesothorium has given good results.

Krause of Berlin reported the successful treatment of small relapses by the Roentgen rays and the value of prophylactic treatment after operation on the breast. In two cases, in which it could be shown that a definite part of the breast had not been irradiated, relapses occurred in these places. The rays must be filtered and tubes under ten We. (this refers to Wehnelt's penetrometer) must not be used.

Perthes of Tübingen referred to a case of carcinoma of the lips treated by him by radiotherapy which had remained cured for more than six years.

Fritsch of Breslau discussed Abderhalden's method of serodiagnosis of cancer. He had tried to test its value as an indication for operation. By the use of numerous parallel tests and frequent repetitions of the reaction, it is possible to exclude the principal sources of error, but even then it had only the value of probability and was useful only in connection with the clinical picture. Fritsch believed, however, that even if the scope of application of the reaction is very small, there are cases in which the test can be of service to the clinician, and one is not justified for that reason in rejecting it completely.

Marriages

Caryl Ashby Potter, M.D., St. Joseph, Mo., to Miss Marie Whitney of Brooklyn, N. Y., at Hubbard Woods, Ill., April 4.

Charles Henry Dean, M.D., Northampton, Mass., to Miss Martha Gertrude Jones of Salisbury, Vt., May 6.

Phineas Hilhouse Adams, M.D., to Miss Marguerite La Wall Janvrin, both of New York City, May 5.

David Ralston, M.D., to Mrs. Alice Daly, both of Cadillac, Mich., at Grand Rapids, April 30.

George Enos Miller, M.D., Hammond, Ind., to Miss Eda L. Flasher of Chicago, April 22.

Alford Jay Farnham, M.D., Reinbeck, Ia., to Miss Jean Brown of Traer, Ia., April 29.

Deaths

David William Bulluck, M.D. University of Maryland, Baltimore 1873; a member and once vice-president of the Medical Society of the State of North Carolina; formerly president of the Atlantic Coast Line Surgeons' Association; and at the time of his death president of the Onslow Medical Society; local surgeon at Wilmington, N.C., for the Atlantic Coast Line; a member of the Board of Directors of the Eastern Hospital for the Insane, Goldsboro; and for many years a member of the Board of Health of New Hanover County; died at his home in Wilmington, May 6, from typhoid fever, aged 60.

John Benjamin Lewis, M.D. New York University, New York City, 1853; medical director of the Travelers' Insurance Company, Hartford, for nearly forty-five years; a member of the Connecticut State Medical Society and Association of Life Insurance Medical Directors; surgeon of the Fifth Connecticut Volunteer Infantry, later Brigade Surgeon and medical director of the department of West Virginia during the Civil War; brevetted lieutenant colonel in 1865 for 'faithful and meritorious service'; died at his home in Hartford, April 26, aged 82.

Charles N. Field, M.D. College of Physicians and Surgeons in the State of New York, 1870; a Fellow of the American Medical Association, and American Academy of Ophthalmology and Laryngology; a member of the American Association for the Advancement of Science, and the American Association of Railway Surgeons; a veteran of the Civil War, in which he served in the Hospital Corps of the First New York Volunteer Infantry; a practitioner of Jefferson, Ia., since 1871; died at his home in that place, May 7, from pneumonia, aged 71.

Samuel G. Gray, M.D. University of Pennsylvania, Philadelphia, 1863; a member of the Medical Society of the State of Pennsylvania; and once vice-president of the Lancaster County Medical Society; assistant surgeon of the Twenty-Ninth Pennsylvania Volunteer Infantry and surgeon of the Twentieth Pennsylvania Cavalry during the Civil War; from 1875 to 1878, a surgeon on Atlantic liners; died at his home in Landisville, May 2, from heart disease, aged 76.

William Edmond Weber, M.D. College of Physicians and Surgeons, in the city of New York, 1894; a Fellow of the American Medical Association; chief inspector of the milk department of the New York Board of Health; attending physician to the German Hospital; and lecturer on pediatrics in the New York Polyclinic; died suddenly in a subway station in New York City, May 7, aged 46.

Thomas Corwin McCaughey, M.D. Rush Medical College, 1868; one of the most prominent practitioners of central Illinois; a Fellow of the American Medical Association; and once president of the Vermilion County (Ill.) Medical Society; a veteran of the Civil War; died at his home in Hoopeston, Ill., May 6, from heart disease, aged 73.

Archie Eli Brimmer, M.D. Rush Medical College, 1910; of Minneapolis; a Fellow of the American Medical Association; died in the Eitel Hospital, Minneapolis, May 4, from meningitis, a week after a surgical operation, aged 31.

Lucius Lavoisier Lamar, M.D. University of Texas, Galveston, 1903; a Fellow of the American Medical Association; a specialist on diseases of the eye, ear, nose and throat; died at his home in Florence, Texas, May 2, aged 35.

Henry Cabell Tabb, M.D. Medical College of Virginia, Richmond, 1860; surgeon in the confederate service throughout the Civil War; for twenty years medical director of the Life Insurance Company of Virginia; died at his home in Richmond, Va., May 7, aged 75.

Patrick J. McKeown, M.D. Bellevue Hospital Medical College, 1890; a Fellow of the American Medical Association; formerly health officer of Long Island City; and a member of the staff of St. John's Hospital; died at his home in Long Island City, May 3, aged 53.

Frederick W. Meddaugh, M.D. Jefferson Medical College, 1909; of Williamsport, Pa.; a member of the Medical Society of the State of Pennsylvania, aged 26, was killed in an automobile accident on the Lycoming state road near Williamsport, May 5.

John A. Brobst, M.D. College of Physicians and Surgeons, Baltimore, 1885; secretary to Secretary of the Navy Thompson, at the time of the settlement of the Nova Scotia fisheries claim; died at his home in Allentown, Pa., May 4, from septicemia, aged 61.

Elmore Y. Munsell, M.D. Starling Medical College, Columbus, Ohio, 1869; for twenty-one years a practitioner of Portland, Ore., but for the last four years a resident of Ocean Park, Wash.; died in the Good Samaritan Hospital, Portland, April 28, aged 75.

James Ney Wright, Jr., M.D. University of Michigan, Ann Arbor, 1882; a member of the board of liquor license commissioners of Licking County, Ohio; formerly county auditor; died at his home in Newark, Ohio, about May 5, aged 55.

William H. Minnich, M.D. College of Physicians and Surgeons, Baltimore, 1890; a member of the Medical Society of the State of Pennsylvania; for eight years jail physician of York County; died at his home in Dallastown, Pa., May 1, aged 49.

James S. Black, M.D. For sixty-three years a practitioner of Ohio; died at the home of his son in McConnellsville, Ohio, February 6, from uremia, aged 87.

James O. Stewart, M.D. McGill University, Montreal, 1880; for many years a practitioner of Cazaville, Que.; died at his home in Montreal, February 20.

Elva M. Thornberry, M.D. Western Pennsylvania Medical College, Pittsburgh, 1887; died at his home in Barnesville, Ohio, March 13, aged 49.

Norman Glenn Parker, M.D. Cleveland University of Medicine and Surgery, 1897; formerly of Onawa, Iowa; died in Port Royal, Pa., March 15.

Oliver L. Blachly, M.D. Jefferson Medical College, 1887; formerly of Sparta and Wilkinsburg, Pa.; died at his home in Pasadena, Cal., April 18.

Nelson Loar, M.D. Physio-Medical College, Cincinnati, 1867; died at his home in Bloomington, Ill., April 29, from senile debility, aged 74.

Annie M. Brown, M.D. Women's Medical College of the New York Infirmary, 1880; died at her home in Brooklyn, N. Y., April 30, aged 72.

Harry Atherton Smith, M.D. Medical School of Maine, Brunswick, 1890; died at his home in West Roxbury, Boston, April 27, aged 47.

Eugene Frederick Pearce, M.D. Long Island College Hospital, Brooklyn, 1883; died at his home in Brooklyn, April 30, aged 55.

George H. W. Ryan, M.D. McGill University, Montreal, 1899; died at his home in Vermillion, Alta., February 21, aged 40.

John C. Peyton, M.D. Jefferson Medical College, 1866; of Winter Garden, Fla.; died in Orlando, Fla.; February 27, aged 72.

James W. Long, M.D. Meharry Medical College, Nashville, 1899; died at his home in Texarkana, Texas, April 25, aged 41.

James J. Brown, M.D. University of Toronto, Ont., 1887; died at his home in Owen Sound, Ont., February 24, aged 53.

George B. Loring, (license, Utah, five years' practice, 1894); died at his home in Monroe, Utah, April 25, aged 49.

Walter Cartier, M.D. Laval University, Montreal, 1905; of Coteau Station, Que.; died in Montreal, January 28.

T. R. Dice, M.D. St. Louis Eclectic Medical College, 1876; died at his home in Utica, Mo., April 19.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

THE TURNOCK MEDICAL COMPANY

The Lynott-Katz-Read Mail-Order Medical Concern Declared Fraudulent by the Federal Authorities

The Turnock Medical Company was a fraudulent mail-order concern operating from Chicago. May 6, 1914, the Postmaster-General issued a *fraud order* against the Turnock Medical Company and Dr. T. Frank Lynott, the medical employee who is described in the Turnock "literature" as the "specialist in charge." At the time the federal authorities put the quietus on this fraud, the Turnock Medical Company was receiving about four thousand letters a day from the gullible sick, and its income is said to have been approximately $350,000 in the last year of its existence. It has been doing business eight years.

For some years past, the Propaganda Department has been keeping itself informed on the methods of the Turnock Medical Company and T. Frank Lynott. Until comparatively recently, the men behind the Turnock Medical Company are said to have been:

Eugene Katz, President and Treasurer.
George J. Katz, Vice-President.
Sam D. Katz, Secretary and Manager.

In the operation of a mail-order medical concern a knowledge of medicine is not necessary. A due appreciation of the gullibility of the sick; an absence of moral sense; an utter disregard for truthfulness and common honesty—these are the essential requirements to make a commercial success of concerns like the Turnock Medical Company. And the Turnock concern apparently fulfilled these requirements.

THE PERSONNEL

Eugene Katz is said to have been a professional advertisement writer before he went into the fraudulent medical mail-order business. George J. Katz and Sam D. Katz were indicted by a federal grand jury in January, 1914, on the charge of operating a fraudulent mail-order concern under the style of "Dr. G. B. Abbott." The "Sam Katz Oxygen Catarrh Treatment" is another fraud operated from the same address as the Abbott swindle.

THE COMMERCIAL VALUE OF URIC ACID

The Turnock Medical Company sometimes advertised under its own name and sometimes under the name of Dr. T. Frank Lynott. Its advertising slogan was "Uric Acid." All diseases, according to the Lynott-Turnock theory, are due directly or indirectly to uric acid. During the past three or four years letters have been sent to the Turnock Medical Company under various names and from widely separated places, describing various hypothetical cases. One letter was sent in describing a well-advanced case of cancer of the rectum. According to Lynott's "diagnosis," this unfortunate individual had an "excess of uric acid." Wrote the quack:

> "I am positively certain in my own mind that I have the method to cure you. The suffering that you have undergone in the past must convince you that there is no time to be lost. . . . A person at your age has still a long and happy life ahead if the disease can be gotten rid of now."

A letter mailed from another part of the country contained one of Lynott's "symptom blanks" on which check marks had been placed against the following symptoms: (1) "Too frequent desire to urinate;" (2) "Pain or soreness in the bladder;" (3) "Pain or soreness in the kidneys." This hypothetical party, according to Lynott's "diagnosis," also suffered from an "excess of uric acid," and Lynott wrote, per stock letter "A":

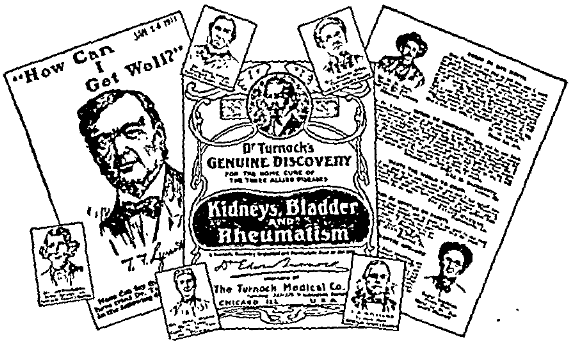
"I am positively certain in my own mind that I have the method to cure you. The suffering that you have undergone in the past must convince you that there is no time to be lost. . . . A person at your age has still a long and happy life ahead if the disease can be gotten rid of now."

A third letter, sent from still another address, merely asked about the Turnock Medical Company's "treatment." Its writer, too, was told he had excessive uric acid!

During the past three or four years, physicians have sent us letters received by some of their patients who had "fallen for" the Turnock advertisements, and in every instance, no matter what the ailment of the patient, Lynott was "positively certain" in his "own mind" that he could cure the patient. This merely meant, of course, that in common with all mail-order medical concerns, the Turnock Medical Company had an elaborate series of "form letters" that were sent out to the prospective victims that answer advertisements. The much vaunted "individual treatment" received by people who write to such concerns consists in turning the letter over to mailing clerks who see that a given stock letter is sent to the unfortunate sufferer and dupe—prospective or present.

THE FREE TRIAL TREATMENT

The scheme of the Turnock Medical Company was to advertise a free treatment, "I *am giving away $10,000 worth* of medicine," declared Dr. T. Frank Lynott. The Turnock advertisements also contained a list of eighteen "symptoms" which "uric acid sufferers" might be expected to have. Symptom 1 was "Pain in the Back." As this symptom bears about as much relation to "excessive uric acid" as it does to that equally vague and uncertain condition known as "female trouble," it might be counted on to catch many "suckers." Symptom 5 was "Prostatic Trouble"—also, we are asked to believe, the result of "excessive uric acid." Symptom 8 was "Pain or Soreness under the Right Rib," Symptom 10, "Constipation or Liver Trouble" and Symptom 13, "Pain in the Neck or Head." The all-inclusive character of these symptoms made it easy to impress the general public with the idea that "excessive uric acid" was the *bête noire* of existence; hence, send for a "free trial treatment" of Dr. Turnock's Genuine Discovery!



Some pages and clippings from the book "How Can I Get Well," sent out by the Turnock Medical Company.

THE "FOLLOW-UP" SYSTEM

Possibly the best way of describing the methods pursued by the Turnock Medical Company will be to give in some detail one of a number of cases that have been followed up by The Journal.

A postal card was written by a man we will call Mr. Blank, from a town in North Carolina. It asked the Turnock Medical Company for information regarding its "treatment," but gave no description of a case, either real or hypothetical. By return mail back came form-letter, "T. F. L. 2," reading in part as follows:

"*My dear Mr. Blank:*—Your request came duly to hand, and knowing that you must be anxious to hear from me, I hasten to reply enclosing the promised free matter. But I want to give your case careful and conscientious study, as it presents many interesting phases to me, and rather than give a hasty diagnosis, I prefer to give the symptoms, etc., complete thought for a few days, and then let you hear from me in detail with confidential facts.

"In the meantime, in order that you should not be kept waiting, and so that you may have your system nicely prepared for treatment, I enclose herewith a free supply of Dr. Turnock's Genuine Discovery in the form of general specific Uric Acid medication, which will apply to your case for the present in a general way. I will then have completed my regular and confidential diagnosis and found out just exactly what you need in every particular as to ingredients, medications, diet, special advice, etc., so that I can then recommend with sincerity a reliable and accurate personal specific for your cure. I am also anxious to compare your case with others I have treated in the past 25 years."

The "free" matter referred to in the letter consisted of a book entitled, "How Can I Get Well?" and a small cardboard box containing a number of small sugar-coated tablets. Four days later came form-letter, "T. F. L. 3," reading in part as follows:

"*My dear Friend:*—You were expecting to hear from me before this, but several points came up that required attention and delayed me. I have now completed a most careful personal examination of your case and can say with all truth that I feel absolutely sure you are curable. In the short space of a letter a full and detailed description of your symptoms, or the causes and effects of your afflictions could not be given. But in the pictorial pamphlet "How Can I Get Well?" that I sent you with the free trial treatment, I have more fully described your diseases, which are *Kidney Trouble and Excess of Uric Acid, on pages, 14 & 15, 32 & 36 & 33 & 49.*

"I am positively certain in my own mind that I can cure you. The *suffering that you have undergone in the past* must convince you that there is no time to be lost. The older a disease like yours gets the more misery and pain it causes. The sooner it is cured the more days you have to enjoy life, and the longer your life will last. A person at your age has still a long and happy life ahead if the disease can be got rid of now.

"Realizing how necessary it is that you shall begin your cure at once, I have sent the full course of home treatment direct to your address to-day by mail at our expense. This will give you a chance to see what you are getting. Most doctors would ask you for the money first, but that takes time, and you have no time to lose; other doctors send treatment by Express C. O. D., but this is neither honorable nor fair, as you can't see what you are getting and it adds to your expense. So I thought that the Direct Delivery would be the better way, and I know you will agree with me and appreciate it."

PLEASE REMIT THREE DOLLARS

For the "full course of home treatment" the victim thus has foisted on him unasked, he is requested to remit $3. Should he not care to take the treatment, he is told: "Do not return it until I send postage as it may get lost." The reason for this warning is twofold: First, it permits the victim to retain the pills during a period in which he will be bombarded with insistent follow-up letters from Lynott urging him to take the "treatment" and in time reducing the price asked for it; second, as it costs four cents postage to send these pills, it would be a losing game for Lynott to request their return as the "$3 treatment" was not worth four cents. As a matter of fact, of all the cases The Journal has investigated—and they are many—in not one did the Turnock Medical Company ever send the four cents for the return of their "treatment" for which they asked $3.

The "full course of home treatment" came in a cardboard box about 4 inches square and 1 inch deep. In this box were three other boxes; one of them contained about 30 oblong, sugar-coated tablets, colored a vivid vermilion; box 2 contained about the same number of tablets of the same size colored a rich purple; box 3 contained two kinds of tablets, one labeled "Constitutional Remedy," and the other, "Vitalizer Remedy." The "Constitutional Remedy" consisted of twenty-three small chocolate-coated tablets, laxative in character and apparently nothing more than the common aloin, belladonna and strychnin pill. The "Vitalizer Remedy" consisted of fourteen sugar-coated tablets bright orange in color. No matter what the case, the victims all received the same purple, scarlet, orange and chocolate-coated tablets and the same set of follow-up letters.

If no notice was taken of the letters or pills, form-letter "T. F. L. 4" came in due time. Dr. Lynott was feeling pained at the patient's indifference. He wrote:

My dear Mr. Blank:—Excuse me for writing you so soon again, but it seems strange I have not had a definite answer from you since sending the special treatment. I ask you is this fair? Is this treating me as kindly as I treated you? I want you to consider the 101 names of cured people, covering every Uric Acid disease that I guarantee to cure. Now could I have so many testimonials from total strangers if Dr.

Turnock's Genuine Discovery were not a wonderfully curative home treatment?

"I have made you the lowest price I can possible make you. It is lower than you can get such treatment for anywhere else in the world. It is less than one-half what thousands of others have paid in the past. It is simply the price of one visit to any reputable physician. And I include a whole treatment of medicine and I charge nothing extra for my professional services. What more can you ask?

"I have given you endless proof of what the treatment will do for you, have legally guaranteed to cure you and have offered you a treatment that has always sold for five dollars for just three dollars, and if you now want to know about my own and the Company's responsibility—its financial ability to carry out guarantees—then write to the Colonial Trust and Savings Bank, to Chas. J. Grady, or A. E. Fechter, his successor, one of the most prominent druggists in Chicago, to Roberts & MacAvinche, among the best known concerns of its kind in the world, and to your friends who live in Chicago."

Thus, and much more; closing with the statement: "I look for your order just as fast as the mails can bring it." Continued silence brought "T. F. L. 5," in which Lynott says:

"*My dear Mr. Blank:*—I enclose herewith a copy of a letter I addressed to you some days ago, as I have not heard from you regarding the matter. Whether the other letter reached you or not, do me the favor to read the attached letter over again. I believe it will convince you that you ought to pay for the treatment and begin to use it at once.

Some of the numerous letterheads used at different times by the Lynott-Turnock outfit.

"This is no trifling matter, and that is why I took it upon myself to send you the treatment without loss of time. That proves my sincerity and friendship to you.

"This treatment is suited to your case. I feel positive it will cure you. I have successfully cured hundreds upon hundreds of people, so why should you doubt that I know how to cure you?

"I specialize in uric acid ailments such as yours and their complications. I specialize therefore in the very disease that you have. Why should I not be able to cure you? Are the tens of thousands I have treated no advantage in my favor?"

NOW OFFERED AT HALF PRICE

"Do not ignore this matter," continues Dr. Lynott. "It may be that the span of your life depends on my treatment." In form-letter "T. F. L. 6," Turnock cuts the price in half.

"*My dear Mr. Blank:*—Have been trying to find a reason why you have not yet accepted the treatment recently sent you at my expense. Have come to the conclusion that perhaps you cannot afford to pay out three dollars just at this time, and yet you do not feel like writing me about it and asking for a reduction.

"If that is so I will at once put you in a position where you can easily get the treatment. I know that sick people have many expenses, and I want to help them in every way I can and do all in my power to lighten their burdens. So by following the advice contained in this letter you will be safe. It is this:

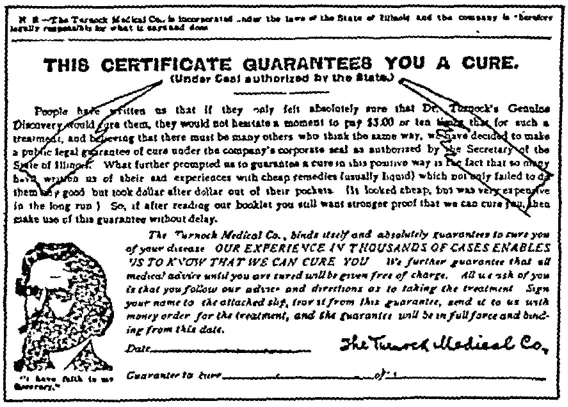
"Send me one dollar and a half and take the treatment. This is a reduction of one-half, or fifty per cent. I do this because I believe you need the treatment, and I hope you will appreciate the reduction."

Then another wait, and a printed form comes offering the "treatment" for "Only One Dollar." If this, too, fails to bring results, the Turnock Medical Company charges the form-letters and pills up to profit and loss, drops the name from its mailing list and presumably rents or sells it to other concerns in similar fraudulent businesses.

In the memorandum of Assistant Attorney-General Lamar to the postmaster-general recommending the issuance of a fraud order against the Turnock Medical Company and Dr. T. Frank Lynott, most of the facts already given were brought out. In addition, the following came to light:

THE READ-KATZ ARRANGEMENT

The individual claiming to be the sole owner of the Turnock Medical Company at the time the case was brought up for trial was one George H. Read. He was represented in this case by Attorney W. Knox Haynes of Chicago, the same lawyer, by the way, that appeared in defense of the Marjorie Hamilton and Texas Guinan frauds. Doctors Frederick A. Jefferson and James W. Hall of Chicago appeared as expert witnesses for the Turnock fakery. While Eugene Katz was alleged to have withdrawn from the Turnock business, the following quotation from the assistant attorney-general's memorandum throws an interesting light on the real facts of the case:



N. B.—The Turnock Medical Co. is incorporated under the laws of the State of Illinois and the company is therefore legally responsible for what it says and does.

THIS CERTIFICATE GUARANTEES YOU A CURE.
(Under Seal authorized by the State.)

People have written us that if they only felt absolutely sure that Dr. Turnock's Genuine Discovery would cure them, they would not hesitate a moment to pay $3.00 or ten times that for such a treatment, and believing that there must be many others who think the same way, we have decided to make a public legal guarantee of cure under the company's corporate seal as authorized by the Secretary of the State of Illinois. What further prompted us to guarantee a cure in this positive way is the fact that so many have written us of their sad experiences with cheap remedies (usually liquid) which not only failed to do them any good but took dollar after dollar out of their pockets. (It looked cheap, but was very expensive in the long run.) So, if after reading our booklet you still want stronger proof that we can cure you, then make use of this guarantee without delay.

The Turnock Medical Co., binds itself and absolutely guarantees to cure you of your disease OUR EXPERIENCE IN THOUSANDS OF CASES ENABLES US TO KNOW THAT WE CAN CURE YOU We further guarantee that all medical advice until you are cured will be given free of charge. All we ask of you is that you follow our advice and directions as to taking the treatment Sign your name to the attached slip, tear it from this guarantee, send it to us with money order for the treatment, and the guarantee will be in full force and binding from this date.

*Date*________________ The Turnock Medical Co.

*Guarantee to cure*________________ *of*________________

"I have faith in my discovery."

Every fraudulent mail-order concern issues a certificate guaranteeing either a cure or a return of your money; the Turnock Company was no exception. Here is a reduced reproduction of the Turnock Medical Company's "guarantee certificate." Note the impression the concern attempted to give that the guarantee was authorized by the State.

"Mr. Read claims that he purchased the business from Katz in May for a consideration of $125,000, represented by twenty-five notes payable over a period of about one year. Mr. Read admitted that the net receipts of the business for the year preceding the alleged sale were approximately $70,000, that the stock is on deposit as security for the notes; that there was an understanding that the notes were to be allowed to run at interest after maturity if not paid at that time; that a report is made each month relative to the business by Read to Katz, and that they have had a number of interviews since the alleged transfer although Katz has since then been a resident of New York. On the advice of counsel, Mr. Read declined to produce any of the monthly reports which he has made to Katz. Read admitted further that he draws from the business as a salary, $10,000 a year. It is apparent that Katz has retained more or less of an influence and interest in the conduct of the business."

ALL "TREATMENTS" THE SAME

The postal inspectors who investigated the Lynott fraud submitted under assumed names a number of the symptom

> "I am positively certain in my own mind that I have the method to cure you. The suffering that you have undergone in the past must convince you that there is no time to be lost. . . . A person at your age has still a long and happy life ahead if the disease can be gotten rid of now."

A third letter, sent from still another address, merely asked about the Turnock Medical Company's "treatment." Its writer, too, was told he had excessive uric acid!

During the past three or four years, physicians have sent us letters received by some of their patients who had "fallen for" the Turnock advertisements, and in every instance, no matter what the ailment of the patient, Lynott was "positively certain" in his "own mind" that he could cure the patient. This merely meant, of course, that in common with all mail-order medical concerns, the Turnock Medical Company had an elaborate series of "form letters" that were sent out to the prospective victims that answer advertisements. The much vaunted "individual treatment" received by people who write to such concerns consists in turning the letter over to mailing clerks who see that a given stock letter is sent to the unfortunate sufferer and dupe—prospective or present.

THE FREE TRIAL TREATMENT

The scheme of the Turnock Medical Company was to advertise a free treatment, "I am giving away $10,000 worth of medicine," declared Dr. T. Frank Lynott. The Turnock advertisements also contained a list of eighteen "symptoms" which "uric acid sufferers" might be expected to have. Symptom 1 was "Pain in the Back." As this symptom bears about as much relation to "excessive uric acid" as it does to that equally vague and uncertain condition known as "female trouble," it might be counted on to catch many "suckers." Symptom 5 was "Prostatic Trouble"—also, we are asked to believe, the result of "excessive uric acid." Symptom 8 was "Pain or Soreness under the Right Rib," Symptom 10, "Constipation or Liver Trouble" and Symptom 13, "Pain in the Neck or Head." The all-inclusive character of these symptoms made it easy to impress the general public with the idea that "excessive uric acid" was the *bête noire* of existence; hence, send for a "free trial treatment" of Dr. Turnock's Genuine Discovery!

Date ______________ The Turnock Medical Co.

Guarantee to him ______________ *of* ______________

"I have faith in my discovery."

Every fraudulent mail-order concern issues a certificate guaranteeing either a cure or a return of your money; the Turnock Company was no exception. Here is a reduced reproduction of the Turnock Medical Company's "guarantee certificate." Note the impression the concern attempted to give that the guarantee was authorized by the State.

"Mr. Read claims that he purchased the business from Katz in May for a consideration of $125,000, represented by twenty-five notes payable over a period of about one year. Mr. Read admitted that the net receipts of the business for the year preceding the alleged sale were approximately $70,000, that the stock is on deposit as security for the notes; that there was an understanding that the notes were to be allowed to run at interest after maturity if not paid at that time; that a report is made each month relative to the business by Read to Katz, and that they have had a number of interviews since the alleged transfer although Katz has since then been a resident of New York. On the advice of counsel, Mr. Read declined to produce any of the monthly reports which he has made to Katz. Read admitted further that he draws from the business as a salary, $10,000 a year. It is apparent that Katz has retained more or less of an influence and interest in the conduct of the business."

ALL "TREATMENTS" THE SAME

The postal inspectors who investigated the Lynott fraud submitted under assumed names a number of the symptom coupons from the Turnock advertisements checking different symptoms. They, in common with others who answered advertisements, received the regular follow-up letters, the "free trial treatment" of pills and the unasked for, "full course of home treatment." On this point the assistant attorney-general said:

"The evidence shows that the treatment sent in all of these cases was the same, and consisted of well-known drugs which are sometimes prescribed by physicians as diuretics, expectorants, stimulants and cathartics, dependent on the conditions present in each individual case. The 'free treatment' consisted of the same medicine, but in smaller quantity. The medicine thus sent out is intended for the elimination of excessive uric acid from the system, and is of some value for this purpose when prescribed in accordance with the individual requirements of each case.

"That the symptoms set forth above may arise from a number of causes is such a well-recognized fact as hardly to require expert testimony to prove. However, the physicians who were present at the hearing were examined on this point, and they agreed that none of these symptoms, taken alone or in combination with any or all of the others necessarily indicated an excess of uric acid in the system but might be due to other conditions requiring treatment of another kind. On this point there was no contrariety of evidence. While the physicians who appeared voluntarily at the request of this office asserted that there were many other causes of these symptoms just as common, if not more so, than excessive uric acid, the experts employed by the respondents stated that, although there were many *other causes. excessive uric acid was the most common.* In view of their admission, however, that there are many other causes, it follows that even on this theory, excessive uric acid is the cause in only a small percentage of the cases. The physicians called by this office also testified that some of the diseases represented by these symptoms were incurable and others curable only by a surgical operation, and that the applicability of this medicine in any case where the symptoms were in fact due to excess of uric acid was dependent on the conditions present in each individual case. Whether, then, this treatment would be of any value whatsoever in any case where prescribed in accordance with this system is entirely a matter of chance. I am satisfied from the evidence that all of the above facts were at all times well known to the respondents.

Send Me a Dollar!

When you wrote us for treatment we sent you some free. Then when your symptom blank came, we decided that you urgently needed regular treatment. What did we do? Keep writing you letters about it asking for money in advance, and wasting your time *and postage, while giving your disease a chance to get worse?*

N O !

We sent you the treatment you needed and prepaid the charges. The company took the chances, not you How did we come out of the transaction? Very badly. We lost all around. We went to great expense and got nothing for it. Now we ask you kindly to

Help Pay Expenses

It is costly to send out remedies the way we do And yet we believe it is the only way to do it in justice to those who are sick It gives them a "square deal" in seeing what they are getting. All we ask is a square deal.

The symptom blank you filled out showed clearly that you needed the kind of treatment I sent you Then why not take it? It is as good today as it ever was. Take it, and send the company only one dollar and thus help pay expenses, while at the same time helping yourself to be cured Or, if you know of a friend who needs such a treatment, make them a present of it. How can you spend a dollar to better advantage?

I won't say another word. Send the dollar and take the treatment. Make your remittance to

DR. T. FRANK LYNOTT
OF THE TURNOCK MEDICAL CO.

Photographic reproduction, greatly reduced, of the last of the follow-up series in which Lynott offered to take one dollar for the treatment for which he first asked three dollars. If this offer were not accepted it did not pay Lynott to send the four cents postage necessary for the return of the pills.

REPRESENTATIONS FALSE AND FRAUDULENT

"I *therefore find that the above* representations calculated to lead the reader to believe that, if he is suffering from any of the symptoms set forth in the advertisement, he is in need of the medicine offered by this company; that the company can and will diagnose the disease from which the addressee of the form-letters is suffering, by this system; that it has determined the disease or diseases from which the addressee is suffering; that it has determined that the addressee is curable, and that it knows that the medicine is suited to the case—are all false and fraudulent. I also find that the representations contained in the advertisement *calculated to lead the reader to believe* that he may obtain free a remedy for his disease is a fraudulent device intended to induce the sending to the company of names and addresses without making the promised return therefor, but instead thereafter advising the writer in effect that the remedy necessary for his cure must be paid for. I also find from the evidence that this treatment prescribed in this way is not of the efficacy represented in the advertising matter of this concern, and that it is in fact not different from, or better than, other treatments used for the same purpose."

NOT A MATTER OF OPINION

Like every quack and every exploiter of fraudulent "patent medicines" when caught in the net of the law the argument was advanced that the curative value of the Turnock Treatment was a matter of "opinion." To quote again from the attorney-general's memorandum:

"In argument and in his brief, Mr. Haynes insists that the question in this case is a question of opinion, and therefore not a proper question for the Postmaster-General to determine one way or the other. The question in the case is *not,* however, as he assumes, *whether or not this medicine* will cure or benefit conditions due to excess of uric acid, but whether or not the company makes false and fraudulent representations of fact in order to accomplish the sale of the medicine; and that it does so is, in my opinion, clearly shown by the evidence. The inevitable result of the system followed by this company in its treatment of disease is the defrauding of a large number of people out of money which they can ill afford to lose for drugs for which they have no need, and in a great many cases a resultant postponement of proper treatment, in some instances until too late."

In view of these facts Judge Lamar reported to Postmaster-General Burleson:

"I find that this is a scheme for obtaining money and property through the mails by means of false and fraudulent pretenses, representations and promises, in violation of Sections 3929 and 4041 of the Revised Statutes, as amended; and therefore recommend that a fraud order be issued against the parties named in the caption of this memorandum."

As previously stated, the mails were closed to the Turnock Medical Company and Dr. T. Frank Lynott on May 6, 1914.

[A business that brings in $350,000 a year is, it seems, not one to be abandoned without a fight. The Chicago papers announce, as we go to press, that the Turnock Medical Company has filed a petition for injunction to prevent the enforcement of the fraud order.]

The Average Mind.—The perfect physical form in man or woman is much more sought than found. The perfect mental form is even more rare. The best to hope for in the average man, from nature and nurture, is to have a right judgment in all things. In how few of us is this consummation reached! One philosopher made the comforting remark that "every man has a sane spot somewhere." Burton, in his survey of humanity in the famous "Anatomy of Melancholy," concludes that the whole world is mad, and needs a journey to Anticyra (where the best hellebore, a specific against madness, was grown).—Osler: Specialism in the General Hospital.

Some Statistics Concerning the Academic Careers of Medical Students

To the Editor:—The records of state board examinations, while they give an excellent idea of certain end-results obtained in the medical schools of this country, convey no hint of what might be termed the academic morbidity and mortality. Like a case of well-developed chronic disease, they represent merely the terminal stages, and there is no way of tracing through them the various metamorphoses that resulted in the finished product. The following figures are based on the records of the students entering the Yale Medical School from 1896 to 1908. They cover a period during which the requirements for admission were changing, and this gives an opportunity to compare students who were prepared to enter the medical school under different systems as to their capacity to grasp the subject of medicine and to pass through the medical school with or without conditions. Of the 518 students whose records were analyzed, 52.8 per cent. were graduates of high or preparatory schools; 16.2 per cent. entered on examination; 14.6 per cent. had spent from one to three years in colleges or scientific schools, and 16.2 per cent. were graduates of colleges or scientific schools.

Of this entire number, 58.8 per cent. graduated from the Yale Medical School, 85.9 per cent. of them in the minimum required period; 11.8 per cent. in one year more, and 2.2 per cent. in two years more than the minimum required period. These figures possess a certain interest on account of the different attitude toward graduation which is taken in European countries and in the United States. In Great Britain—if we may judge from the report of Mr. Hallett—it is expected that a considerable proportion of medical students will not graduate in the minimum required period of study. On the Continent of Europe, too, it does not appear to be regarded as disgraceful for a student to fail in his first attempt to obtain a degree, and the course may be voluntarily extended beyond the minimum required period. In this country, however, a certain stigma seems to attach to the individual who fails to obtain his degree in the minimum time of study required. It is a grave question whether this is not a distinctly fallacious attitude, largely because it fails to take into account the fact that there is a marked disparity in the capabilities of different men, even though they have equivalent preliminary training, to master in a fixed time the essentials of a difficult subject like medicine. On the other hand, it seems possible that the European attitude of allowing a man to continue studying year after year, even though he appears to lack the mental attainments necessary for the mastery of medicine, is perhaps too liberal an attitude, and not conducive to the best interests of the students or of the profession.

STATISTICS REGARDING 305 GRADUATES OF YALE MEDICAL SCHOOL

Preliminary Qualifications	Time Required to Graduate			Honor Winners				Completed Course Without Conditions
	4 Years	5 Years	6 Years	All Kinds	Cum Laude	Gold Medal	Keese Prize	
Grads. of High Schools.	81.6	15.0	3.4	12.6	8.6	5.4	2.8	44.8
Entered on Examination	86 0	11.7	2.3	18.6	18.6	6.9	2.3	46.5
1 to 3 Years of College.	89.2	10.8	...	28.5	25.0	14.8	7.1	53.5
College Graduates......	96.7	3.3	...	42.6	36.0	11.8	9.8	65.5

Comparing the four groups of students with regard to their ability to complete their medical course in the minimum required time, it is found that 81.6 per cent. of the high-school graduates, 86 per cent. of those entering on examination, 89.2 per cent. of the college undergraduates, and 96.7 per cent. of the college graduates completed the course in the minimum amount of time. None of the college undergraduates or graduates took more than an extra year to obtain a degree, while 3.4 per cent. of the high-school graduates, and 2.3 per cent. of the students entering on examination took two extra years to do so.

It is interesting to compare the record of the different types of entrants with regard to the obtaining of honors, prizes or honorable mention. Of the total number of graduates, 20.9 per cent. obtained one of these forms of distinction, and of this group 12.6 per cent. were entrants from high schools; 18.6 per cent. entrants on examination; 28.5 per cent. undergraduates of colleges, and 42.6 per cent. graduates of colleges. The distinction awarded in this school are the *cum laude* degree, the conferring of which is based on the entire record of the student; the Campbell gold medal, which is given the student having the highest marks for the complete course, and the Keese prize for the best thesis, which is not usually awarded unless theses containing original work are submitted. So far as the *cum laude* awards are concerned, 8.6 per cent. of the high-school entrants who graduated received the *cum laude*, 18.6 per cent. of those entering on examination, 25 per cent. of the college undergraduates, and 36 per cent. of the college graduates. The Campbell gold medal was won by high-school entrants in 5.4 per cent., by those entering on examination in 6.9 per cent., by college undergraduates in 14.8 per cent., and by college graduates in 11.8 per cent. The Keese prize was won by high-school entrants in 2.8 per cent., by those entering on examination in 2.3 per cent., by college undergraduates in 7.1 per cent., and by college graduates in 9.8 per cent. These figures bring out several suggestive points, of which two stand out rather prominently: (1) the success of men entering on examination over the high-school entrants in obtaining the *cum laude* degree, and (2) the great preponderance of college undergraduates and college graduates among those who won the Keese prize, which, as stated, is based on evidence of ability to do research work. The success of the examination entrants is probably due to the fact that many of them were unusually earnest students who had overcome their defects in preliminary education by determined work and who exhibited the same quality of determination in their work as medical students.

Of the total number of students who graduated from the institution, only 50.1 per cent. passed through their entire course without conditions, and here, again, the college undergraduates and college graduates furnished the largest percentage of successful students; 65.5 per cent. of the college graduates and 53.5 per cent. of the college undergraduates passed through without conditions, while only 44.8 per cent. of the high-school graduates, and 46.5 per cent. of those entering on examination were able to do this.

The migration of students who had no conditions to other schools was comparatively small among the high-school and examination entrants, and large among the college undergraduates and graduates. Only 2.5 per cent. of the unconditioned high-school entrants, and 4.7 per cent. of the unconditioned examination entrants went to other schools, while 38.1 per cent. of the college undergraduates, and 14.2 per cent. of the college graduates went elsewhere. This state of affairs is largely due to local conditions, more especially to the existence of the so-called "combined course" in connection with Yale College. As a result of the existence of this course, many men who entered Yale College with the idea of studying medicine, or who resolved to study medicine during their college course, elected the first two years of medicine during their third and fourth college years, and received the A.B. degree at the end of their second year in medicine. Having already spent four years in New Haven, and doubtless influenced to some extent by the supposed paucity of clinical material here as compared to the larger centers, these college men migrated in considerable numbers at the end of their preclinical years.

The number of students who originally entered this institution but subsequently obtained their M.D. degree elsewhere, was 14.8 per cent. of the total entrants, and of this number 46.7 per cent. left here with either past or existing conditions. The number who failed to obtain the M.D. degree elsewhere—so far as can be discovered from an examination of the medical directories—was 26.2 per cent. of the total number of entrants. It would appear from these figures that, roughly speaking, three-fourths of those men who attempt to obtain a medical degree succeed in doing so. This percentage of success, however, is obtained only by the migration of a considerable number of poor students to schools with low standards. It is probable that in many of the poorer medical schools almost all of the student immigrants are of this class. The fact that a considerable proportion of the emigration from this school has not been of this type is due entirely to the local conditions which have already been discussed.

In a general way, these statistics show that the man with college training has a very decided advantage in the study of medicine. It hardly needed figures to show this, but it is of interest to note that figures bear it out. They also suggest that some provision should still be made so that the unusual man, whose preliminary education has not conformed to the set standards, may have opportunity to study medicine without being forced into the low-grade medical school. They suggest that satisfactory provision for the freer migration of medical students is desirable. From experience with a very considerable number of migrants, I believe that a free interchange—at any rate among schools rated in the same class—should be encouraged in the case of good students. These should be allowed to pass from school to school without having to submit to harassing red tape. On the other hand, the migration of lame ducks from one school to another should be discouraged. It is true that the state board examinations weed out the incompetents, but it hardly seems right to allow a person who is obviously unable to meet the requirements of an exacting profession like medicine to spend years in costly preparation only to find himself disbarred from practicing his profession at the end of his period of preparation. It is both kinder and juster to such persons to discourage them during their career as medical students, and while such a policy must of necessity result in occasional mistakes and injustice, it is, we believe, the most desirable one both from the points of view of the medical student, the profession and the public.

George Blumer, M.D., New Haven, Conn.,
Dean, Medical Faculty, Yale University.

A Plea for Certain Medical Officers of the U. S. Army

To the Editor:—The act of Congress approved April 23, 1908, provides for a Medical Reserve Corps of the U. S. Army, and the appointment thereto of the contract surgeons who were then in the service and received the recommendation of the Surgeon-General. The officers so appointed are debarred by this law from retirement, and by various decisions of the War Department and the Attorney-General of the U. S., from receiving credit for their former service as contract surgeons in reckoning longevity pay.

By the act approved March 3, 1911, Congress has granted to the dental surgeons the right to retirement on account of age or disability, as in the case of other officers and credit for time served as contract dental surgeon in computing increased service pay.

The functions of the Medical Corps and the Medical Reserve Corps are one and the same, and the many varied and complex duties which the officers in each corps are required to perform are alike. In spite of the status of the officer in the Medical Reserve Corps, he has the same spirit and pride to uphold the honor and dignity of the profession, to render to his country service of a high standard of excellence and to maintain social consideration; and to the performance of his duties he dedicates himself with the same zeal, industry and faithfulness as his colleagues in the Medical Corps.

The law under which the medical department of the U. S. Army was reorganized in 1908 does the greatest injustice to the officers of the Medical Reserve Corps. They are the only commissioned officers in the Army denied the privilege of retirement. The law relative to the dental surgeon is a good one, a step in advance. He does not get more than he deserves. But comparing service, it is believed that a longer stride should have been made by Congress, with the same effort, and equal provision made for the officer in the Medical Reserve Corps, as he surely is entitled to and should receive the same privileges of retirement for disability or age as the dental surgeon and other officers of the Army.

Do the distinguished gentlemen on the inactive list of the Medical Reserve Corps realize that when they are called to active duty and respond (as they will do), they may be wounded in battle or be incapacitated from disease and rendered physically unable to resume the lucrative practice which they have patriotically relinquished to serve their country, and if such an unfortunate event should occur, the most they could hope for is a meager pension?

The existing law specifically states that no officer of the Medical Reserve Corps shall be entitled to retirement pay (Section 9, Act of April 23, 1908); yet their colleagues in the regular Medical Corps, and dental surgeons, even though just commissioned, are entitled to and will receive retirement under such conditions.

It is believed that the officers of the Medical Reserve Corps, when on the active list, should be accorded the right to retirement on account of age or disability, as in the case of other officers, including dental surgeons, chaplains, veterinarians and pay-clerks; and credit for former services as acting assistant surgeon and contract surgeon in computing increased service pay, the same as is now authorized by law for the dental surgeons.

The following form of a bill should, it is thought, meet the approval of all medical reserve corps officers, whether or not on the active list, as being a fair and justifiable request for the necessary legislation, to place the M. R. C. officer on equality with the dental surgeon.

A BILL TO PROVIDE FOR THE RETIREMENT AND LONGEVITY PAY FOR CERTAIN MEDICAL OFFICERS OF THE U. S. ARMY

Be it enacted by the Senate and House of Representatives of the United States of America, in Congress assembled, That hereafter officers of the Medical Reserve Corps, U. S. Army, on the active list, shall have the right to retirement for age or disability as in the case of other officers.

Sec. 2. That former service as acting assistant surgeon or contract surgeon shall be reckoned in computing the increased service pay of officers on the active list of the Medical Reserve Corps of the Army.

Sec. 3. That all acts or parts of acts in conflict with the provisions of this act are hereby repealed.

F. M. Wall, M.D., Fort Lawton, Wash.

Housing and Sanitation

To the Editor:—Permit me as a member of the American Public Health Association to congratulate you on the editorial which appeared in The Journal, May 9, 1914, p. 1479, on this subject. As the medical adviser of the Canadian Commission of Conservation, I believe most fully in the importance of public health work being carried into the homes of our people. We as sanitarians have been devoting too much work to "the outside of the platter" and must get busy on the inside. Both fields must be worked, but the inside of the home is as an untrodden field. It is, however, the one in which our best work can and should be done.

We have pushed forward medical inspection of schoolchildren, which in the main simply is curative of the ills consequent on the neglect by health authorities of home sanitation in its widest sphere. I am convinced that if health authorities would but enter into this domain, the result would be that the cost of school inspection would be minimized and healthier children would be sent to our schools when the age of tuition begins. This is the proper kind of medical inspection of children.

From a public health point of view, such factors as race influence, eugenics, occupation, poverty, high cost of living and many others have to be considered; but the health of the home and all that it means for life and death is an outstanding factor which seems to have been lost sight of because it has been neglected.

Charles A. Hodgetts, M.D., Ottawa, Canada.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

RECIPROCAL RELATIONS OF PENNSYLVANIA

To the Editor:—With what states does Pennsylvania have reciproca relations?
C. L. N.

Answer.—Arkansas, California, Colorado, Delaware, District of Columbia, Georgia, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Missouri, Nebraska, Nevada, New Jersey, New Mexico, North Carolina, Ohio, Vermont, Virginia, West Virginia, Wisconsin and Wyoming.

MASTITIS IN MUMPS—INFLUENCE OF DRUGS ON THE MAMMARY GLANDS

To the Editor:—If mastitis develops as a complication of mumps, does it usually impair the function of the glands later?

2. If so, what is the best treatment?

3. What preparations or measures will stimulate the glandular activity of the mammary glands?

C. B. Creech, M.D., Middleburg, Ky.

Answer.—1. No. We find no reference to such effects and conclude that they must be unknown or extremely rare.

2. Ordinarily symptomatic treatment for ordinary mastitis.

3. It is doubtful whether any drugs have an influence on the mammary glands. The extract of the pituitary gland has been recommended as a stimulant to the secretion of milk, but the evidence as to this is not conclusive.

THE PLACENTIN SKIN REACTION IN PREGNANCY

To the Editor:—Can you give me the technic for Engelhorn and Wintz's skin reaction in pregnancy as abstracted in The Journal, May 9, 1914, p. 1514? The method of preparation of placentin is particularly wished.
Kenneth M. Lynch, M.D., Charleston, S. C.

Answer.—The method of preparation of placentin is not given in the paper abstracted, which is the only publication on this subject. The authors assert that they wish to perfect the method before giving a complete description. Inoculation is made in the same way as is the tuberculin reaction of von Pirquet, and the reaction is most completely developed by thirty-six hours after the inoculation. It consists of inflammatory swelling and reddening with a light-brown discoloration of the surrounding skin..

BOOKS ON HYGIENE AND SANITATION

To the Editor:—Can you recommend a good practical book on hygiene and sanitation that would cover the duties of a medical officer in a semitropical town of 15,000 population?
Charles Hardwicke, M.D., Hospital "El Aguila," Minatitlan, V. C., Mexico.

Answer.—Harrington's "Practical Hygiene," published by Lea & Febiger, Philadelphia, price $4.50, and Rosenau's "Preventive Medicine and Hygiene," published by D. Appleton & Co., New York, price $6, are excellent works. Readers of German may consult R. V. L. Abel's "Handbuch der Praktischen Hygiene," published by G. Fischer, Jena, 1913, two volumes.

DOSAGE OF TYPHOID VACCINE FOR CHILDREN

To the Editor:—Please give me the accepted dose of typhoid vaccine for children.
C. A. Shore, M.D., Raleigh, N. C.

Answer.—The dosage of typhoid vaccine for children is given by Frederick F. Russell in The Journal, Feb. 1, 1913, page 344, as follows:

"The dosage is based altogether on body-weight and not on age. The child is given that portion of the adult dose which his weight bears to the average adult weight, 150 pounds. If the fraction proves inconvenient, a little more, rather than less, is administered. As with adults, the best time for inoculation is 4 o'clock, or later, in the afternoon, since any reaction will then come after bedtime."

Book Notices

COMMUNICABLE DISEASES: AN ANALYSIS OF THE LAWS AND REGULATIONS FOR THE CONTROL THEREOF IN FORCE IN THE UNITED STATES. By J. W. Kerr, Assistant Surgeon-General, and A. A. Moll. Paper. Price, 50 cents. Pp. 699. Public Health Bulletin No. 62. Washington: Government Printing Office, 1914.

This is a compilation and analysis of federal and state laws and health board regulations of the United States concerning communicable diseases. The report says that, using the United States census figures as a basis, it may be estimated conservatively that at least 25 per cent. of the deaths in this country are due to communicable diseases. This means 300,000 deaths and over 3,000,000 cases. The importance of having proper laws and regulations, efficiently enforced, for preventing to the greatest possible extent these diseases is therefore apparent. The report is highly valuable as showing what has already been accomplished by the national and state governments in providing these laws and also the need for further legislation, for uniformity and for enacting into laws many measures for disease prevention which are now only the regulations of health boards. It is said that while in many states authority is conferred on state boards of health to establish regulations for disease-prevention, yet it is undeniable that there are advantages in having the sanitary policy of a state expressed in unmistakable form by the legislature. Although health board regulations may represent the best sanitary principles, they embody knowledge not common to the general mass of the people, while the acts of the legislature are adopted after more or less general discussion by the public and are, therefore, more popularly understood. The *Bulletin* contains a brief analysis of federal laws with regard to quarantine and the management of communicable diseases and then analyzes the laws of the various states with reference to each contagious or infectious disease, showing what states have laws covering these diseases and what the laws actually mean. Following this there is an appendix containing court decisions concerning the enforcement of health regulations and laws, and extracts bearing on communicable diseases from the laws of the various states and the national government. A study of the *Bulletin* by the various state authorities would reveal their own shortcomings and assist them in efforts to secure better and more uniform regulations, better organizations for their enforcement and for cooperation with the health authorities of other states. Efficient disease prevention largely depends on such cooperation.

It is a great convenience to have this material brought together into one volume and Public Health Bulletin 62 is, therefore, a most valuable publication. It may be procured from the superintendent of documents at the government printing office, Washington, D. C., at 50 cents per copy.

PATHOGENIC MICRO-ORGANISMS. A Text-Book of Microbiology for Physicians and Students of Medicine. (Based on Williams' Bacteriology.) By Ward J. MacNeal, Ph.D., M.D., Professor of Pathology and Bacteriology in the New York Post-Graduate Medical School. Cloth. Price, $2.25. Pp. 462, with 213 illustrations. Philadelphia: P. Blakiston's Son & Co., 1914.

This work is brought out as a successor to the well-known book of Williams. The arrangement has been changed, most of the text rewritten, and molds, bacteria, protozoa and filterable viruses are included. The work is divided into three sections, on bacteriologic technic, general biology of pathogenic micro-organisms, and specific micro-organisms. The descriptions are clear and the book is amply illustrated. The relations of bacteria to disease, and the theories of immunity and pathogenic action are thoroughly considered. The manual ought to be of service to practical physicians wishing to review the subject as well as to students. That it has been brought quite up to date is shown by the inclusion of the latest communications of Flexner and Noguchi on the virus of epidemic poliomyelitis.

Miscellany

Experience of United States Medical Officer with Mexican Wounded

Although war has not been declared between the United States and Mexico, and no fighting has taken place between the troops of the two nations except at Vera Cruz, some United States Medical Corps men have had experience in taking care of the wounded Mexican soldiers of both sides as the result of battles along the border. Captain Louis C. Duncan of the Medical Corps, U. S. Army, in the *Military Surgeon,* gives a graphic account of his experience in taking care of the wounded of both sides at the battle of Ojinaga, a town on the Rio Grande opposite Presidio, Tex. Between three and five thousand men on each side were engaged in this battle, and there were about fifteen hundred camp-followers, including men, women and children, many of whom were wounded or sick and had to be given attention. The medical organizations of the Federals was not adequate, the rebels perhaps having the better. The Red Cross organization was early on the ground at Presidio with a small force, and the United States forces furnished a few men in charge of Captain Duncan. With the meager facilities at hand on the part of both, and with much hurried and strenuous work, those needing attention were cared for. The wounds were of all sorts. Out of 200, 25 per cent. were serious, involving gunshot wounds of the head and face, perforations of chest and abdomen and fractures of the femur and other long bones, as well as spinal injuries. Of these the wounds of the spine, of the femur and of the cranium in the order named were regarded as most serious, considering the facilities for handling them. Wounds of the chest were not regarded as particularly serious, and perforating wounds of the abdomen were all treated on the expectant plan and did astonishingly well. Serious hemorrhage was rare in any case. From his experience Captain Duncan draws the following conclusions with reference to the handling of the wounded in battle:

1. No case is non-transportable — as far as a field-hospital.
2. Hemorrhage seldom has to be treated at dressing-station or field-hospital.
3. A white tent, sheltering from thirty to forty-five wounded, is far preferable to our present dark, heavy, cumbersome hospital tent. A tent weighing 600 pounds will take the place of five hospital tents weighing 1,200 pounds, and be far more convenient.
4. Tincture of iodin, dressings, soap, some antiseptic, like compound solution of cresol, a few splints and a pocket-case are all the things needed for 99 per cent. of the wounded in the field.
5. A dressing-station for slightly wounded is entirely unnecessary. The regimental aid stations should dress all these men and send them back to the firing-line. A separate divisional station divides the personnel and confuses the wounded.
6. Gunshot wounds of the spine are the most difficult of all cases to care for and the most fatal.
7. Perforating wounds of the cranium are very serious, require much care and in nearly 50 per cent. of cases result in death.
8. Perforating wounds of the thorax by small-caliber bullets are not usually serious. They are generally easy to handle and about 90 per cent. of them will end in recovery.
9. Perforating wounds of the abdomen are not so fatal as has been believed. With the minute modern missile, nearly always at long range, the abdomen is often perforated without serious damage. These cases require little attention and 50 per cent. of the patients will recover — if not meddled with.
10. Fractures of the femur are very difficult to treat in the field. Many will become infected and the ultimate results will be bad. They should not be treated in the field but should be removed early before the bone begins to unite. Wounds of the knee are also serious. Fractures of the bones of the leg give little trouble.

11. Wounds of the upper extremities are usually unimportant. The patients walk about and take care of themselves; even assist in caring for others. This is a very important item in the field. One wound of the spine, or fracture of the femur, makes more work than twenty of the arm.

12. The keeping of records in a field-hospital, with wounded coming by the ten or twenty, and at all hours, is a very difficult matter.

13. The organization of a field-hospital into wards, etc., with responsible surgeons and nurses, is absolutely necessary to good work.

14. An army wagon will carry as many patients as an ambulance, and, if properly bedded, with as much comfort; but litters cannot be used and the loading and unloading are very difficult. For all patients able to sit up they are superior to ambulances.

Schedule for Health Survey

W. H. Deadrick, in the *American Journal of Tropical Diseases and Preventive Medicine*, March, 1914, says that the most significant evidence of the results of the modern municipal efficiency movement is the wide-spread consideration of health matters. Public health departments are deservedly being investigated with a view to improvement through constructive criticism. Cities formerly advertising low tax-rates, good railroad facilities and other trade-inducing advantages now call attention to low death- and morbidity-rates, child-welfare and other health functions as commercial assets. Popular ignorance of sanitary principles is still one of the most serious impediments to sanitary progress, and publicity is the remedy. The health survey is the gateway to this publicity, and many cities are having sanitary surveys made. Deadrick has constructed a scheme for such a survey which he believes should prove useful in cities in which an expert is not employed. Such a survey should be under the following heads: organization of the health department; contagious and communicable diseases; tuberculosis; sanitary inspections; street-cleaning; food inspections; meat inspection; water-supply; sewerage and sewage disposal; housing conditions; child welfare; medical inspection of schools; hospitals and clinics; laboratories; vital statistics; death, birth and marriage records and health education, etc. Information collected under each of these departments of municipal health housekeeping should afford a thorough survey of conditions and a basis for improvement.

Intradermal Test for Tuberculosis in Cattle and Hogs

In Bulletin 243 of the University of California, Haring and Bell consider the intradermal method of tuberculin testing of cattle which is said to have many advantages over the usual method. The reaction depends on a swelling at the point of injection and not on a rise of temperature, though the rise may take place at the same time as the swelling, modified, however, by unusual surroundings, such as very hot weather, fatigue from a long journey, etc. The test can be successfully applied to young calves and range cattle, and during the hot season in the interior valleys under conditions that would render the subcutaneous method unsatisfactory. In applying 4,926 intradermal tests and retests to 4,001 head of cattle, 1,614 of which reacted, and checking the results by 1,000 subcutaneous tests and 341 necropsies, Haring and Bell conclude that under average dairy conditions the intradermal test equals the subcutaneous method in accuracy provided a 5 per cent. or stronger solution of alcoholic precipitated tuberculin is used, and the test is performed by an experienced operator. Since none of the tests will detect all the cases of tuberculosis, the combined intradermal and subcutaneous or ophthalmic test is recommended. The intradermal test is especially adapted to the testing of swine. In applying the test it is preferable to use a short needle, not over ¼ inch in length, and in cattle the injection should be made in the fold at the root of the tail. The size of the swelling produced indicates the extent of the reaction.

Medicolegal

Responsibility for Malpractice of Partners and Substitutes

(Lee vs. Moore (Tex.), 162 S. W. R. 437)

The Court of Civil Appeals of Texas in reversing a judgment obtained by the defendant and ordering a new trial, says that if a physician makes provision for the attendance of a competent physician on his patient, he may leave temporarily, but for the unwarranted abandonment of a case at a critical period resulting in increased pain and suffering on the part of the patient, he will be held liable in damages. In this case the question was as to the liability of a physician for the malpractice of a substitute furnished by him.

The plaintiff had arranged with the defendant to attend his wife in childbirth. One night the defendant was summoned, pronounced the pains false, and went home. When called again next morning by telephone, he replied that he could not come, but would send another physician, a Dr. Hardin. The court is of the opinion that, even though it should be conceded that common carriers in furnishing a physician to treat injured passengers, etc., and persons rendering gratuitous services in employing a physician to attend on a sick or injured person are only required to exercise ordinary care to select a skilful and competent physician, yet, under the facts of this case, the duty of the defendant to furnish the plaintiff a physician to attend on his wife possessing that degree of knowledge, skill, and care which physicians practicing in that city and vicinity possessed, was absolute. If it could be said that Dr. Hardin was not an assistant of the defendant in the treatment of the plaintiff's wife, and was not a general partner of the defendant in the practice of medicine, yet that he was a special partner in the treatment of the case, or was acting under his employment to do so, could not very well be gainsaid. At any rate, the defendant, being a physician himself, and having by contract undertaken the treatment of Mrs. Lee, and having secured the services of Dr. Hardin to relieve himself of the necessity of attending her himself and to serve his own interests, the defendant would not be allowed to say that, in such case, the duty resting on him in the selection of a substitute physician was simply that of ordinary care.

Whether the plaintiff was under the influence of intoxicating liquors and exhibited a pistol in such a threatening manner towards Dr. Hardin while he was waiting on the plaintiff's wife as to alarm or excite Dr. Hardin to such an extent as that the same contributed to the failure, if any, of the physician to use ordinary care and skill in the treatment of the plaintiff's wife, was an issue made by the evidence, which should have been submitted to the jury for their determination, with instructions that an affirmative finding on it would entitle the defendant to a verdict in his favor.

Preliminary Proof Required for Roentgenograms

(Ligon vs. Allen (Ky.), 162 S. W. R. 536)

The Court of Appeals of Kentucky reverses a judgment for alleged malpractice in the treatment of a fractured humerus because of error in the admission of certain roentgenograms when the necessary preliminary requirements had not been established. The court says that the witness merely stated that he took the photographs. He did not state that they correctly represented what he saw, or how they were taken, or that he had ever taken a roentgenogram before, or knew anything about how they ought to be taken. No assurance was given as to the character or accuracy of the Roentgen-ray machine, or its condition or working order. While it may not be necessary to establish all of these facts in order to make roentgenograms admissible in evidence, the accuracy of the photographs must be established, for, if they do not show what the witness saw, they have no place in the case. The rule is recognized by all the authorities that when the witness fails to make a roentgenogram admissible by testifying to its accuracy, it is not admissible and should be rejected.

Book Notices

Communicable Diseases: An Analysis of the Laws and Regulations for the Control Thereof in Force in the United States. By J. W. Kerr, Assistant Surgeon-General, and A. A. Moll. Paper. Price, 50 cents. Pp. 699. Public Health Bulletin No. 62. Washington: Government Printing Office, 1914.

This is a compilation and analysis of federal and state laws and health board regulations of the United States concerning communicable diseases. The report says that, using the United States census figures as a basis, it may be estimated conservatively that at least 25 per cent. of the deaths in this country are due to communicable diseases. This means 300,000 deaths and over 3,000,000 cases. The importance of having proper laws and regulations, efficiently enforced, for preventing to the greatest possible extent these diseases is therefore apparent. The report is highly valuable as showing what has already been accomplished by the national and state governments in providing these laws and also the need for further legislation, for uniformity and for enacting into laws many measures for disease prevention which are now only the regulations of health boards. It is said that while in many states authority is conferred on state boards of health to establish regulations for disease prevention, yet it is undeniable that there are advantages in having the sanitary policy of a state expressed in unmistakable form by the legislature. Although health board regulations may represent the best sanitary principles, they embody knowledge not common to the general mass of the people, while the acts of the legislature are adopted after more or less general discussion by the public and are, therefore, more popularly understood. The *Bulletin* contains a brief analysis of federal laws with regard to quarantine and the management of communicable diseases and then analyzes the laws of the various states with reference to each contagious or infectious disease, showing what states have laws covering these diseases and what the laws actually mean. Following this there is an appendix containing court decisions concerning the enforcement of health regulations and laws, and extracts bearing on communicable diseases from the laws of the various states and the national government. A study of the *Bulletin* by the various state authorities would reveal their own shortcomings and assist them in efforts to secure better and more uniform regulations, better organizations for their enforcement and for cooperation with the health authorities of other states. Efficient disease prevention largely depends on such cooperation.

It is a great convenience to have this material brought together into one volume and Public Health Bulletin 62 is, therefore, a most valuable publication. It may be procured from the superintendent of documents at the government printing office, Washington, D. C., at 50 cents per copy.

Pathogenic Micro-Organisms. A Text-Book of Microbiology for Physicians and Students of Medicine. (Based on Williams' Bacteriology.) By Ward J. MacNeal, Ph.D., M.D., Professor of Pathology and Bacteriology in the New York Post-Graduate Medical School. Cloth. Price, $2.25. Pp. 462, with 213 illustrations. Philadelphia: P. Blakiston's Son & Co., 1914.

This work is brought out as a successor to the well-known book of Williams. The arrangement has been changed, most of the text rewritten, and molds, bacteria, protozoa and filterable viruses are included. The work is divided into three sections, on bacteriologic technic, general biology of pathogenic micro-organisms, and specific micro-organisms. The descriptions are clear and the book is amply illustrated. The relations of bacteria to disease, and the theories of immunity and pathogenic action are thoroughly considered. The manual ought to be of service to practical physicians wishing to review the subject as well as to students. That it has been brought quite up to date is shown by the inclusion of the latest communications of Flexner and Noguchi on the virus of epidemic poliomyelitis.

The intradermal test is especially adapted to the testing of swine. In applying the test it is preferable to use a short needle, not over ¼ inch in length, and in cattle the injection should be made in the fold at the root of the tail. The size of the swelling produced indicates the extent of the reaction.

Medicolegal

Responsibility for Malpractice of Partners and Substitutes

(Lee vs. Moore (Tex.), 162 S. W. R. 437)

The Court of Civil Appeals of Texas in reversing a judgment obtained by the defendant and ordering a new trial, says that if a physician makes provision for the attendance of a competent physician on his patient, he may leave temporarily, but for the unwarranted abandonment of a case at a critical period resulting in increased pain and suffering on the part of the patient, he will be held liable in damages. In this case the question was as to the liability of a physician for the malpractice of a substitute furnished by him.

The plaintiff had arranged with the defendant to attend his wife in childbirth. One night the defendant was summoned, pronounced the pains false, and went home. When called again next morning by telephone, he replied that he could not come, but would send another physician, a Dr. Hardin. The court is of the opinion that, even though it should be conceded that common carriers in furnishing a physician to treat injured passengers, etc., and persons rendering gratuitous services in employing a physician to attend on a sick or injured person are only required to exercise ordinary care to select a skilful and competent physician, yet, under the facts of this case, the duty of the defendant to furnish the plaintiff a physician to attend on his wife possessing that degree of knowledge, skill, and care which physicians practicing in that city and vicinity possessed, was absolute. If it could be said that Dr. Hardin was not an assistant of the defendant in the treatment of the plaintiff's wife, and was not a general partner of the defendant in the practice of medicine, yet that he was a special partner in the treatment of the case, or was acting under his employment to do so, could not very well be gainsaid. At any rate, the defendant, being a physician himself, and having by contract undertaken the treatment of Mrs. Lee, and having secured the services of Dr. Hardin to relieve himself of the necessity of attending her himself and to serve his own interests, the defendant would not be allowed to say that, in such case, the duty resting on him in the selection of a substitute physician was simply that of ordinary care.

Whether the plaintiff was under the influence of intoxicating liquors and exhibited a pistol in such a threatening manner towards Dr. Hardin while he was waiting on the plaintiff's wife as to alarm or excite Dr. Hardin to such an extent as that the same contributed to the failure, if any, of the physician to use ordinary care and skill in the treatment of the plaintiff's wife, was an issue made by the evidence, which should have been submitted to the jury for their determination, with instructions that an affirmative finding on it would entitle the defendant to a verdict in his favor.

Preliminary Proof Required for Roentgenograms

(Ligon vs. Allen (Ky.), 162 S. W. R. 536)

The Court of Appeals of Kentucky reverses a judgment for alleged malpractice in the treatment of a fractured humerus because of error in the admission of certain roentgenograms when the necessary preliminary requirements had not been established. The court says that the witness merely stated that he took the photographs. He did not state that they correctly represented what he saw, or how they were taken, or that he had ever taken a roentgenogram before, or knew anything about how they ought to be taken. No assurance was given as to the character or accuracy of the Roentgen-ray machine, or its condition or working order. While it may not be necessary to establish all of these facts in order to make roentgenograms admissible in evidence, the accuracy of the photographs must be established, for, if they do not show what the witness saw, they have no place in the case. The rule is recognized by all the authorities that when the witness fails to make a roentgenogram admissible by testifying to its accuracy, it is not admissible and should be rejected.

MISSISSIPPI STATE MEDICAL ASSOCIATION

Forty-Seventh Annual Meeting, held at Columbus, April 14-16, 1914

The President, Dr. L. C. Feemster of Tupelo, in the Chair

Acute and Chronic Arthritis

Dr. John B. Elliott, Jr., New Orleans: I have found the classification of Barker of great value in the differential diagnosis of the arthritides. Briefly, it is as follows: (*a*) Arthritis of the severe nervous diseases. (*b*) Arthritis due to gout. (*c*) Arthritis Deformans. (*d*) Arthritis due to infections. (*e*) Chronic primary progressive arthritis (rheumatoid arthritis).

DISCUSSION

Dr. J. S. Ullman, Natchez: Acute rheumatic fever is something we hear a great deal about but rarely see. I think a great many cases spoken of as acute rheumatism or chronic rheumatism, are simply the manifestations of trouble in some other part of the body.

Diagnosis of Early Pulmonary Tuberculosis

Dr. C. H. Cocke, Asheville, N. C.: The means of diagnosis are within the reach of all. We should treat each suspect as though he were tuberculous until we have proved the contrary. Physical examination is all-important. The von Pirquet test is of no great value after the second year of life, unless it be negative.

DISCUSSION

Dr. A. J. Williams, Gulfport: For the past few years, physicians living in the small towns have been in the habit of relying on microscopic examination in order to make a diagnosis. I have often had patients go to another doctor, who would tell them that they did not have tuberculosis. Had the other doctors stripped these patients, I am sure they would not have differed with me.

Public Health or Preventive Medicine

Dr. J. H. Portwood, Kosciusko: Physicians should all serve as the advance-guard of the sanitary army. They should preach the prophylaxis of tuberculosis, typhoid and malaria. They should teach that there is a real danger in measles and that not every patient recovers. They should encourage a general campaign for sexual purity and teach the possibility of physiologic continence.

DISCUSSION

Dr. W. S. Leathers, University: I want to emphasize the paramount importance of proper sewage disposal at the country house. A great deal has been said this afternoon with regard to the prevention of different diseases, typhoid, *tuberculosis*, etc., and yet we find out in the country that over 50 per cent. of the homes have no proper provision for disposing of the waste from the home. In many counties, over 40 per cent. of the schools have no conveniences.

Technic for Operation for Ovarian Cysts

Dr. F. D. Smythe, Memphis, Tenn.: The incision should be a long one. In cases in which the cyst is very large, the patient weak and anemic, with embarrassed respiration and heart action, the operation should be done in two steps: the abdomen should be incised down to the tumor and gauze inserted between the tumor and parietal peritoneum to produce union of surfaces; the cyst may be evacuated a few days later.

DISCUSSION

Dr. J. C. Culley, Oxford: There is one thing which I always advise a beginner to do and that is to make a long *incision, because you can see better how to remove the cyst* without fear of doing damage. Sometimes the peritoneum is adherent to the cyst, and if you are not careful you will go right on into the peritoneum and are apt to have a recurrence. The removal of the cyst is better accomplished by the use of the trocar, and that very slowly. Also, in removal of the cyst intact, the fluid often slips back into the abdominal cavity, and that should be protected with gauze.

Pellagra a Curable Disease

Dr. M. O. Shivers, Colorado Springs, Colo.: Put the patient to bed in a cool, dark room. Diet, climate and arsenic (hypodermatically or intravenously) are our weapons. Remember that the pellagrin, no matter how slight the attack, is seriously ill.

DISCUSSION

Dr. W. L. Little, Wesson: Last summer I treated about fifteen cases. I used sodium cacodylate. Not a patient died.

Dr. A. J. Carter, Ellisville: When shall we be able to say that the patient is cured?

Dr. M. O. Shivers, Colorado Springs, Colo.: My first patients were treated three years ago. So far, out of this first series, I have had no recurrences. They were of the bad class—persons that were vomiting, and had mental symptoms.

Diseases Transmitted by Milk and Milk Products

Dr. W. H. Rowan, Jackson: Milk may be a source of disease by carrying it from cow to man or from man to man, or it may act as a factor because of a diminution or an increase in its inherent qualities. A large percentage of Mississippi dairy cows are tuberculous. When cows respond to the tuberculin test, 41 per cent. will show the bacilli in the milk. Typhoid and scarlet fever and diphtheria are transmitted by milk. Our fly-infested towns, with their notorious disregard of the sanitary privy, are in a bad way. The amount of human excreta drunk and eaten in the average Mississippi town is amazing.

DISCUSSION

Dr. D. M. Malloy, Sulligent, Ala.: Dr. Rowan has stated that bovine tuberculosis can be transmitted from cow to man. This is proved particularly in the Philippine Islands, where the milk-supply is derived almost entirely from the carabao, the water-buffalo. Tuberculosis is almost unknown among these animals. The only cow's milk which reaches the Philippines is the condensed milk which is sterilized and contains no organisms. The fact that the carabao is not susceptible to tuberculosis, the fact that bone tuberculosis is due almost entirely to bovine infection, and the further fact that bone tuberculosis is unknown in the Philippines, would seem to establish that it is transmitted in the milk-supply from cow to man.

Tumors of the Breast

Dr. W. G. Gill, Newton: All tumors of the breast are suspicious and should be treated as cancerous until a competent pathologist has pronounced them benign. The best procedure is to remove them and send them to a pathologist; then it does not make any difference in the prognosis what sort of a report he sends you.

DISCUSSION

DR. M. O. SHIVERS, Colorado Springs, Colo.: It is a mistake to remove any tumor and send it to a pathologist. Statistics have shown that in cases in which the tumor was taken out and the breast left four or five days to be removed, the secondary operation is of no value—that few of these women live; so few that it seems absolutely unnecessary to go back after a pathologist has stated that it is carcinoma. So, if there is anything in a woman's breast to require operation at all, that breast should be removed.

(To be continued)

MEDICAL SOCIETY OF THE STATE OF NEW YORK

One Hundred and Eighth Annual Meeting, held in New York City, April 28-30, 1914

The President, DR. WILLIAM FRANCIS CAMPBELL, Brooklyn, in the Chair

Officers Elected

The following officers were elected: President, Dr. Grover Wende, Buffalo, N. Y.; vice-presidents, Dr. Myron B. Palmer, Rochester; Dr. S. W. S. Toms, Nyack, and Dr. Robert M. Elliott, Willard; secretary, Dr. Wisner R. Townsend, New York, reelected; treasurer, Dr. Alexander Lambert, New York, reelected.

Next place of meeting, Buffalo, April 27, 28 and 29, 1915.

DR. WISNER R. TOWNSEND, the secretary, recommended that the delegates to the American Medical Association be requested to favor the passage of a resolution calling on the Trustees to pay the traveling expenses of the delegates to the meetings of the American Medical Association.

Oration on Surgery: Kinetic Chain for Transformation of Latent Energy

DR. GEORGE W. CRILE, Cleveland, Ohio: If our conclusions are sound, then in the kinetic system we should find an explanation of many diseases, and having found an explanation we may find new methods of combating disease. The organs of the kinetic system are the brain, adrenals, liver, muscles and thyroid. Energy is appropriated by the body from the physical forces of nature that constitute the environment, and this energy is stored in the body in quantities in excess of the need of the moment. It is the function of the organs of the kinetic system to transform the surplus so stored into action and heat as needed. This mechanism of organs produces fever as well as muscular activity, fever being heat generated to combat disease.

Deficiency in one of the organs of the kinetic chain causes alike loss of heat, loss of muscular and emotional action, of mental power, and of the power of combating infection. From this we are able to understand the muscular weakness following fever; we can understand why the senile have neither muscular power nor strong feverish reaction; why long-continued infections produce pathologic changes in the organs constituting the kinetic system. Physical or mental shock caused by pain, fear, rage or exercise causes an impairment of the kinetic system because shock means the transformation of potential energy into heat or action. It is desirable, therefore, that unnecessary or too severe shocks be avoided, and the first step in the avoidance of shocks has been made possible by the knowledge of the kinetic system.

Exophthalmic Goiter and Its Treatment

DR. JOHN ROGERS, New York: The first stage is simple hypertrophy; the second stage is that of more or less hypothyroidism; the third stage is that of hyperthyroidism. After hyperthyroidism comes exophthalmic goiter. If the disease lasts long enough the exophthalmic goiter is followed by a fifth stage, a myxedematous condition. The irregular types of exophthalmic goiter can be grouped into different stages which are prolonged in a given case. As to the prognosis in exophthalmic goiter, over 80 per cent. of deaths occur in the exophthalmic stage rather than in the stage of hyperthyroidism. The apparent cause of thyroid abnormalities is fatigue, a simple hypertrophy which is so common, with multiplication of glandular elements in response to demands put on the thyroid which are greater than the normal organ can supply. The antithyroid serum seems to be the best conservative medical treatment. It should not be preserved in except for a short time. The "hyper" cases can be cured much better by ligation of the vessels. I ligate all four of the thyroid arteries and tie off the tip of each upper pole.

DISCUSSION

DR. MARTIN B. TINKER, Ithaca: The diseased condition is limited chiefly to the thyroid in the early stages of the disease. In many cases physicians allow patients to go on with thyroid trouble until they get a dilated heart or are on the verge of insanity, until they have cirrhotic changes in the kidney and liver and other secondary results, and they are confused by the secondary conditions which arise as the result of the thyroid poisoning. If the disease were recognized early many lives might be saved. I have urged on many occasions that the treatment of hyperthyroidism should be undertaken early before serious trouble has occurred in other parts of the body. Within a year two patients came to me who have since gone to insane asylums. Whether or not the insanity could have been prevented in the early stages if treatment had been undertaken, no one can tell, but there is good reason to believe that if patients were taken early enough they might be saved many of the results which occur later.

DR. T. B. BARRINGER, New York: I generally find in these cases that there has been a history of overwork. In 195 cases the history of overwork has doubled a history of fright in those sudden cases that have developed within a few weeks or a few months. These patients faint without the slightest provocation. In this group there have been various disorders of menstruation, such as delayed menstruation and too frequent menstruation; sometimes profuse menstruation has been complained of more than amenorrhea. A large percentage of this group have had the infectious diseases. A proportion of them have had adenoids and enlarged tonsils, and appendicitis. A high percentage of them are anemic. The early cases can be cured by prescribing prolonged rest.

Value of the Various Tests for Determining Functional Activity of Kidney

DR. JAMES N. VANDER VEER, Albany: The so-called phlorizin test is too sensitive. Phlorizin indicates the amount of kidney parenchyma which is capable of functionating. As to the methylene-blue test, only 50 per cent. of the drug is excreted, and it appears as chromogen in the urine, requiring the use of acetic acid and boiling to demonstrate it at this time. This test is too prolonged to be used advantageously. Letters received from 150 surgeons show that from 60 to 70 per cent. use the phenolsulphonephthalein test when they operate on patients. Others use various tests. No more striking evidence of the keen desire for increased accuracy in diagnosis and prognosis in surgical work is to be found than in the persistent and laborious attempts made in order to arrive at a trustworthy method of estimating the functional value of the kidney. Failure of renal function is responsible for a certain proportion of the death-rate.

DISCUSSION

DR. M. W. WARE, New York: The statistics of Young and Freyer when there were no functional tests of the urinary tract were just as good then as now. I recall years ago when Young reported 100 prostatectomies with no deaths, and he did not make use of functional tests.

DR. GIBBONS, New York: I have operated in a great many cases of cancer of the breast without making use of functional tests of the kidney, and none of the patients died on the table or as the result of the operation; but I packed all around the chest with hot towels. It is a matter of having sense not to operate on dying patients. A friend of mine used to say that if the pathologist said cancer, the patient would live; if he said the disease was not malignant the patient would die.

Dr. Paul Pilcher, Brooklyn: I believe in the value of the phenolsulphonephthalein test. During the past year or so we have lost patients by operating when it seemed to us that if we had been warned beforehand that there was something wrong with the kidneys, we might not have operated, or if we had waited and prepared the patients properly, and operated some time later, life might have been saved. Many a patient will be saved by our knowing which of the kidneys is doing the better work.

Dr. Edwin Beer, New York: I agree with Dr. Vander Veer and Dr. Pilcher that functional tests, properly interpreted, will save a great many lives. I am convinced that practically all these tests have their indications and are of value, and by carrying them out we shall prevent a great many deaths which would otherwise follow operations.

Transfusion of Blood, Direct and Indirect

Dr. John A. Hartwell, *New York:* In hemorrhage transfusion is of value, provided it is done properly. Transfusion in cases of ectopic gestation in which rupture has occurred, in gastroduodenal ulcers and in typhoid is indicated and is valuable. I encourage transfusion in the more advanced cases of splenic anemia, pernicious anemia and the severe grades of anemia of unknown origin. Transfusion as a therapeutic agent in pernicious anemia has been of only temporary value. Transfusion is a valuable aid in the treatment of septic conditions, although the results reported by some have been disappointing.

DISCUSSION

Dr. George W. Crile, Cleveland: Dr. Hartwell did not refer to transfusion of blood in acute surgical shock, or in those patients on whom, through emergency, it is necessary to perform a major operation. There is no question whatever but that in acute surgical shock direct transfusion of blood has given the greatest amount of relief and will revive a patient better than any other method. I have used it many times in acute traumatic cases.

Dr. David J. Kaliski, New York: It has been our practice to make preliminary blood-tests in all cases before transfusion, and by this means we have been able to rule out all accidents during transfusion which might occur from hemolysis, from agglutination or from both. A Wassermann test is made in every case to rule out syphilis.

Dr. Robert H. M. Dawbarn, New York: I have recently obtained remarkable results in this class of cases by the addition of large doses of ergot to the saline solution. There is not a single case on record of death from an overdose of ergot, and it has been given in large doses in cases of congestive headaches. The dose is half an ounce of ergotol with from about 1,800 to 2,000 c.c. of normal saline.

LOUISIANA STATE MEDICAL SOCIETY

Thirty-Fifth Annual Meeting, held at New Orleans, April 20-23, 1914

The President, Dr. Fred J. Mayer, Opelousas, in the Chair

Diseases of Aorta, with Special Reference to Aneurysm

Dr. George S. Bel, New Orleans: Almost all aneurysms of the aorta are the result of syphilis. The lesion is primarily in the outer muscular wall and consists of a gummatoid infarction. We do not know what percentage of patients who have syphilis develop syphilitic aortitis, but undoubtedly it is quite common and frequently unrecognized, as shown by necropsy. The essential signs and symptoms of syphilitic aortitis are precordial pain, paroxysmal dyspnea, tachycardia, increased pulsations of vessels of neck, dilatation of aorta and positive Wassermann. It is important to treat all cases early and properly in order to avoid the formation of aneurysm. Weeks and often months precede the actual aneurysmal formation after the syphilitic aortitis began, which, in most of the cases, affords an opportunity for the clinician to recognize the specificity of the aortic disease, and thereby anticipate the formation of aneurysm by instituting syphilitic treatment.

DISCUSSION

Dr. J. B. Guthrie, New Orleans: Without careful percussion of the base of the heart in the first interspace, the practitioner is going to fail to diagnose aneurysm. I cannot agree that percussion is the most valuable of all means of physical examination. The importance of percussing the base of the heart in the region of the manubrium sternum cannot be emphasized too much from a diagnostic point of view. We must institute treatment, if possible, in the prophylactic stage. When a certain amount of aortitis exists, with manifest arteriosclerosis in the peripheral arteries, we are not doing our duty to these patients unless we investigate them fully from the point of view of syphilitic disease.

Dr. Adolph Henriques, New Orleans: Undoubtedly we get more information with the Roentgen ray than by any other single means, but in order to secure this information we have to make a proper examination with the fluoroscope and from several directions, front, back, side and the oblique position. If this is done with a knowledge of what constitutes the normal appearance of the aorta, we can recognize 90 per cent. of aneurysms.

Cerebrospinal Meningitis

Dr. Randolph Lyons, New Orleans: In my twenty-two cases there were eleven deaths. One of the fatal cases did not receive any serum, and hence it is omitted. The mortality for the twenty-one cases treated with serum was 47.6 per cent. If three patients who were practically moribund and died in less than forty hours are excluded, the death-rate may be reduced to 38.8 per cent. Of the remaining seven fatal cases, two had complicating pneumonias, and a third acute nephritis. Five of the patients died of uncomplicated meningitis. Unfortunately no post-mortems were obtainable. In the eleven fatal cases, nine patients died in the first week of admission. Even barring the moribund cases, a mortality-rate of 38 per cent. may be considered rather high under serum therapy. The disease, however, was in many of the cases unusually severe. Another factor which may play a part in the mortality-rate is race. Statistics gathered from the recent epidemics in the South and Southwest have uniformly shown a higher death-rate in the negroes than in the whites, though both races had the benefit of the serum. Galveston was the only exception to this rule. This apparent lessened resistance to the disease among negroes may be due less to radical qualities than to insanitary living and ignorance. The negro usually waits until the disease is well advanced before coming to a hospital. Of the eleven patients who recovered, only two showed any after-effects of the disease. One patient was totally deaf and the other partially deaf.

DISCUSSION

Dr. M. L. Graves, Galveston: The mortality mentioned by Dr. Lyons is entirely too high and must be explained on the ground that the patients received the serum treatment either after the disease had progressed too far or other conditions were present that I am unable to account for. The reduction of mortality by the prompt, efficient and repeated serum therapy is very great.

Dr. M. J. Carouse, Point Coupee: I would like to ask the author what he considers a large dose of the meningococcic serum injected into a child or an adult.

Dr. Randolph Lyons, *New Orleans:* In my series of cases we had to deal with adults. I consider large doses of the serum anything over 40 c.c., but it depends on the amount of spinal fluid withdrawn.

Pellagra and Its Treatment

Dr. E. H. Martin, *Hot Springs, Ark.:* In the large majority of cases the salvarsan treatment of pellagra leads to an uninterrupted recovery without unpleasant symptoms. In some cases the intense pains in the lower extremities, and occasionally in the arms, may be very persistent, and such neuritis may continue for a time after the treatment has been completed. This is strictly a pellagrous symptom, as it does not occur in cases of cerebrospinal lues similarly treated. A few cases will be met in which the infection is so intense, although the symptoms may not be correspondingly severe, that little impression seems to be made and the patient finally dies of the disease. If specific treatment is used in all cases you may confidently expect to cure permanently over 80 per cent.

Fisher's Alkaline-Saline Therapy

Dr. J. T. Halsey, New Orleans: Many cases of general edema and of nephritis are not benefited by this alkaline-saline therapy, and a certain proportion of such cases will be unfavorably influenced by it. In spite of my own lack of success in applying this treatment in one case, I shall continue to try it out cautiously but fairly. It should be tried in cases of general edema or nephritis which do not respond to our usual methods of treatment.

Institutional Treatment of Nervous and Mental Diseases

Dr. Charles V. Unsworth, New Orleans: Of paramount importance in institutional treatment is the educational, industrial and moral training. Industrial training should be directed toward encouraging contentment and industry by occupations suitably selected according to individual tastes. Patients should be assisted to lead well-regulated lives, in order that they may be led to forget the irksomeness of confinement, and helped to believe that they are taking some part in the work of the world. In the Louisiana Retreat the results secured from industrial training have been most gratifying.

Summary of Present Status of Osteogenesis

Dr. Isadore Cohn, New Orleans: I have operated on more than sixty animals. Periosteal transplants or flaps have not reproduced bone in a single instance. I do not believe that periosteum is essential to the life and growth of the transplant, nor do I believe that it is essential to the repair of the defects in bone. Periosteum is not an osteogenetic agent. It serves to protect, to guide the growth of and nourish bone. Bone transplants live and grow; they have an inherent osteogenetic function. In the light of our present evidence, there should be a revision in our teaching in regard to the repair of fractures. Callus is not a product of the periosteum, but of the cortex and endosteum. The autogenous bone graft or transplant is destined to a greater field of usefulness.

NEW YORK NEUROLOGICAL SOCIETY

Meeting held April 7, 1914

The President, Dr. Smith Ely Jelliffe, in the Chair

Chronic Progressive Cerebellar Tremor

Dr. J. Ramsay-Hunt: Three cases of this affection have come under my observation, two were advanced cases; the third was of more recent date. In the former the disease had been progressive over a period of six years. It was characterized by a chronic, gradually progressive tremor, coarse and irregular in character, associated with symptoms of asynergia, hypotonia, adiadokokinesis, and the *intermittent asthenia*, an inability to sustain fixed or continuous muscle contractions. All of these symptoms were referred to disturbance of the cerebellar function. The question of multiple sclerosis was an important one in the interpretation of this group of cases. As, however, all the symptoms indicated a disturbance of the cerebellar function, and were slowly progressive, I would regard these cases as representing a well defined and progressive disease of some portion of the cerebellar mechanism. The clinical type I would designate as the *chronic progressive cerebellar tremor*. Such cases have probably been variously classified as hereditary or essential tremor, multiple sclerosis, hysterical tremor, traumatic neurosis and atypical paralysis agitans. The reports of three cases were given.

Insanity among Jews

Dr. A. A. Brill and Dr. M. J. Karpas: From the figures available in literature one could readily see that the sweeping statement made by so many that the Jew was disproportionately afflicted with insanity had never been confirmed by careful statistical data. We examined the statistical data of the admissions to the Manhattan State Hospital for four consecutive years, beginning Oct. 1, 1908, and ending Sept. 30, 1912. The total number of admissions was 5,710 (2,803 men and 2,907 women), of which there were 1,203 Jews, (588 men and 615 women). The Jews thus constituted 21 per cent. of the total admissions. The predominating psychoses among Jewish patients were of the functional type. The highest percentage was found in the manic-depressive group, and second in order was the undifferentiated depressions, the greatest majority of which belonged to the manic-depressive class, and third in order was the dementia praecox group. The relatively high percentage of the imbecility and constitutional inferiority groups might be explained by the fact that these diagnoses were made only too often when a foreign Jew was examined by a physician who was unfamiliar with his language and racial characteristics. The relatively high percentage of the infective exhaustive groups in men may be partially attributed to the poor hygienic conditions at home and in sweat-shops. The general paresis group showed a comparatively high percentage. The Russians, however, found a very low percentage of general paresis among Jews. The explanation lay in the fact that in Russia the orthodox Jews were in the majority, and owing to their rigid religious tenets and early marriages, they led a pure sexual life. The senile and epileptic insanities and psychoses accompanying organic brain diseases showed a relatively low figure, and the alcoholic psychoses represented only 2.5 per cent. of the male alcoholics: there were none among the female admissions.

DISCUSSION

Dr. George H. Kirby: It is important to know that the Italians are bringing in more epilepsy than any other race; that the Irish supply an enormously disproportionate number of alcoholic psychoses, and that the recently arrived Jews furnish a high percentage of dementia praecox, manic-depressive insanity and feeble-mindedness. To determine the incidence of insanity, one should not compare an essentially immigrant population (such as the Jews in New York with the native born population. An immigrant population may be variously constituted. It usually contains a disproportionate number of young adults, and the two sexes might exist in unusual proportions. On the other hand, the native born population contains from one-sixth to one-fifth of children, and has a much larger proportion of middle aged and old people than an immigrant population. One reason why dementia praecox and manic-depressive insanity are relatively more frequent among Jews admitted to the hospitals than the native born is because there were relatively more young adults in the Jew population. As the average age of the immigrant population increases, there will be more cases of paresis, and, later still, more cases of arteriosclerosis and senile dementia among the Jews.

In regard to feeble-mindedness the data available indicates that it is proportionately higher among Hebrews than other races. Among all the cases of imbecility admitted to the Manhattan State Hospital during the past four years, 50 per cent. of them were Jews, whereas this race constituted only 21 per cent. of the total admissions.

Dr. Maurice Fishberg: Great care must be taken in interpreting the statistics of insanity. Ninety-five per cent. of Jews are city dwellers as against only thirty-three per cent. of non-Jews. Urban dwellers have a higher incidence of insanity, and must commit their mental defectives to institutions, whereas in rural populations the rates of insanity are lower and the milder forms of mental alienation are permitted to roam about. The Jews are engaged in financial and commercial pursuits in much larger numbers than the Christians, and this has an influence in the direction of increasing the number of insane among them.

6. **Distribution of Lesions of General Paralysis.**—A graduated review by Orton of the intensity of the lesions of general paralysis in six areas of each hemisphere of 50 unselected cases indicated the following order of severity—frontal, hippocampal, temporal, precentral, postcentral and with markedly less involvement of the occipital. The circle of Willis does not act as a path of ready communication between the carotid and vertebral systems. The hippocampal region receives a part of its blood-supply from the carotid group, thus including within the distribution of the branches of the carotid those areas where the lesions have been found to be prominent and suggesting this vascular system as the basis for the distribution in the typical case.

7. **Amyloid Degeneration of Brain.**—Two cases of general paralysis of the insane, one with a rather typical clinical course, the other presenting symptoms apparently of focal origin which obscured the clinical diagnosis, showed at autopsy, in addition to the usual gross anatomical changes of paresis, the typical histopathologic lesions of the disease. In one case there were added certain proliferations of the cells of vessel walls, indistinguishable from histopathologic lesions of the endarteritic non-paretic type of cerebral lues. Other alterations present in both cases were certain glistening, grayish or "fish-flesh" appearing, homogeneous deposits, visible to the unaided eye and limited chiefly to the cerebral cortex. In one case they were small, for the most part discrete, thickly sown in the frontal and parietal areas and found in other portions of the cortex. In the other case this type of alteration was restricted to a portion of the right calcarine area. Here, however, the macroscopic appearance was that of a confluent mass.

Microscopically, the process was shown to have involved the mesoblastic apparatus by the deposition of stuffs in the walls of blood-vessels which eventually converted them into structureless masses. Many of the apparently extravascular deposits proved to be only residuals of vessels, the lumina of which had became obliterated, or groups of vessels which had coalesced as the space between them had became annihilated by the encroachments of their respectively thickened walls, while the remainder not so classed could be reasonably interpreted as deposits within the meshes of the adventitial net-like proliferations exhibited by many vessels. Moreover, the process brought to light a richer vascularization than is usually shown in the most pronounced type of the atrophic paretic cortex. The study of this rich vascularization in a general way confirmed the contentions of Cerletti, namely, that what heretofore has been looked on as actual vessel proliferation in the brain, in the majority of instances, is more apparent than real.

The microchemic differences which these deposits exhibited led Fuller to conclude that, despite the wide distribution in the first case and the extent to which surrounding structures had been compromised, the process was still in a stage of devolution, with an amyloid degeneration as the goal. The tannin-silver method in demonstrating the connective tissue invasion of nervous structures by a net-like extension of the proliferated adventitia of blood-vessels added not only confirmation of the previous observations of Snessarew and Achucarro, but furnished the final link in the chain of evidence that in these two cases the process played itself out in the mesoblastic apparatus.

20. **Germicidal Action of Ultraviolet Rays.**—Houghton and Davis found that the ultraviolet rays produced by the Cooper-Hewitt mercury arc have a strong bactericidal action. Certain species of bacteria in aqueous suspension, including spore-forming organisms, are killed by exposure to rays. Molds, however, are only partially destroyed by the ultraviolet light. The action seems to be a photo-mechanic process, and is, in all probability, due to absorption of the ultraviolet rays by the bacterial protoplasm. Water, wines, many inorganic and a number of organic substances in aqueous solution, can be sterilized by intraviolet light. Bacterial vaccines require a prolonged action. Proteins and other bodies of high molecular weight interfere with the action of the rays. Turbidity, both organic and inorganic, has a similar action. Color, within certain limits, seems to have no influence.

28. ***Serum Therapy in Septicemia.**—One hundred and eleven* consecutive cases of severe infection in which either the

course and symptoms were those of septicemia, or cultures showed the presence of bacteria in the circulating blood, were studied by Burnham. The mortality of the entire series (111 cases) was 74, or 66.6 per cent. In some of the cases vaccines were used in the treatment. Burnham believes that vaccines are of benefit in many of the cases not overwhelmed at the onset by the severity of the infection, and, clinically, seem to benefit the majority of the cases. Antistreptococcic serum is of great value, especially during the early stage when its bactericidal powers are most pronounced, and if given in sufficient dosage during the period of invasion will often change a systemic bacteriemia into a localized infection. The combination of antistreptococcic serum, used in the early stage of septicemia, together with autogenous vaccines, used as soon as they can be prepared from blood-cultures, seems to be particularly beneficial. If the blood-cultures are sterile, vaccines may be prepared from the local lesion, although this method is unsatisfactory and may lead to errors. Stock vaccines are still less desirable and are of uncertain value.

Burnham warns that neither sera nor vaccines, although they usually do little harm, are free from danger, and the dosage and intervals need to be carefully worked out. Open-air treatment in cases in which cultures are sterile and as an adjunct to vaccine and serum therapy seems to be the best method of increasing the resistance of the patient.

30. **Carcinoma of Appendix.**—One in every 225 of all appendices, and one in every 53 partially or completely obliterated appendices MacCarty and McGrath found were carcinomatous. Thirty-one per cent. were found in association with other abdominal and pelvic conditions.

33. **Ileocecal Tuberculosis.**—Ileocecal tuberculosis Wiener states is usually a primary lesion. The infection takes place either from tubercle bacilli that have been swallowed (milk or sputum) or through the mesenteric glands. Pathologically we distinguish two forms, the ulcerative or enteroperitoneal and the hypertrophic ileocecal tumor. The diagnosis is very difficult owing to the similarity to appendicitis, with which diagnosis most cases come to operation. The two operations to be considered are lateral anastomosis with or without exclusion and resection. In the majority of cases Wiener suggests the lateral anastomosis first, and there will then often be no secondary operation required; or, if required, it will be done under much more favorable conditions. Wiener reports seven cases.

34. **Experimental Study of Intestinal Obstruction.**—In dogs the authors were able to isolate by double ligatures a loop of the duodenum and high jejunum and reestablish the continuity of the alimentary tract about the closed loop; such a condition is rapidly fatal. A fluid collects within the closed loops that is highly toxic, producing, when injected into normal dogs, a reaction much like that of dogs with closed loops. This toxin is believed to be the cause of death. The toxin is formed by the mucosa of the closed loop, some of it being secreted into the lumen and some remaining within the cells of the mucosa. If the closed loops be drained externally, the postoperative course of the animal is altered, but varying degrees of intoxication still are observable, and the presence of toxin within the mucosa of the drained loops is demonstrable. Absorption takes place not only from the loop contents but from the mucosa direct, the latter being a quite important source of intoxication.

There are various possible explanations for the perversion of function that causes the mucosa to become a source of intoxication, but none is yet proved. The fundamental explanation of the change is as yet unknown. It is possible by the repeated injection of sublethal amounts of the toxin to immunize dogs against fatal doses. The parenchymatous organs, spleen, intestinal mucosa, etc., and particularly the liver, seem to be especially concerned in the production of the resistance against the toxin when dogs are immunized. The extract of an immunized dog's liver, properly handled, will destroy the toxin in vitro. The authors believe that the intoxication observed in closed loops is quite similar to that existing in simple obstruction, and that the same toxin is the essential agent causing death in each instance. The establishment of an enterostomy for drainage in clinical cases may not meet all the requirements for successful treatment.

40. **Colloidal Gold Reaction in Cerebrospinal Fluid.**—The present report by Miller and Levy is based on the examination of 210 spinal fluids secured from 171 cases. In 2 of 8 examinations made on 4 cases of purulent meningitis, typical *Verschiebung nach oben* was observed. Two gave reactions analogous to the paretic type, with the noteworthy differences that the supernatant fluid in the low dilutions showed a pink turbidity and the precipitation continued throughout the remaining tubes. Eleven cases of tuberculous meningitis confirmed either by the finding of tubercule bacilli or by autopsy, gave, with one exception, maximum color changes in the higher dilutions. One observation confirms Eicke's statement that in the early stages the reaction may simulate that of syphilis. As the disease advances there is *Verschiebung nach oben.* Of 10 cases of congenital syphilis 3 showed moderate pleocytosis, 5 a positive phase I. Reactions of the luetic type were obtained in 80 per cent. Reactions in the "luetic zone" occurred in 4 out of 5 cases of secondary syphilis. In 11 cases of tertiary syphilis comprising instances of latent syphilis, gummatous lesions and vascular manifestations, a reaction in the luetic zone occurred in 4. In none was there any demonstrable clinical evidence of central nervous system involvement. Several of the individuals were elderly men, who had had their primary infection many years before, and who, in all probability, will never develop cerebrospinal syphilis, tabes or paresis.

All the tabes dorsalis cases showed luetic curves. With 3 exceptions, these were of moderate intensity, yet definite. Thirteen of the 15 fluids from cases of cerebrospinal syphilis examined reacted in the luetic zone, 6 with fairly marked intensity. All of the 49 cases of general paresis gave characteristic paretic curves. The more advanced cases clinically have shown the most striking tests. The authors conclude that the colloidal gold test is essentially a laboratory method. It can be performed rapidly and with a minimal amount of spinal fluid. Extreme care in the preparation of reagents and the cleaning of glassware is imperative. The test is of no aid in the diagnosis of purulent or tuberculous meningitis. It has no advantage over known laboratory procedures in the diagnosis of congenital syphilis. Reactions in secondary and tertiary syphilis are inconstant. Their significance when present is now known. The statement that they indicate the earliest stages of central nervous system involvement lacks proof. The positive reactions observed in the majority of cases of tabes and cerebrospinal syphilis are not characteristic. The authors feel that the reaction peculiar to paresis is sufficiently constant to warrant its use as an aid in the differentiation of this condition from others with which it might be confused.

41. **Acidoses and Their Occurrence in Chronic Renal Disease.**—The essential feature in acidosis, Sellards says, consists in a general impoverishment of the body in bases or in substances which readily give rise to bases, e. g., sodium carbonate. This may be brought about by the loss of bases as such, as in the so-called relative acidosis, or by the neu-

tralization by acids as in the so-called absolute acidosis. In either case the end result is the same and the distinction between relative and absolute acidoses is misleading. The fundamental features of every acidosis which have been established thus far are: 1. An increase in the tolerance of the body to fixed bases. 2. A diminution in the titratable alkalinity of the blood-serum. 3. A diminution in the carbon dioxid of the blood. The excretion of ammonia either in its relative or absolute amounts, Sellards says, does not afford a definite basis for the detection of acidosis. Thus: 1. The ammonia excretion may be normal in acidosis. This may occur in diabetic cases which are free from any suggestion of renal disease. In the nephritic cases in which the ammonia is low in the urine it is probable that there is no increase in the quantity of ammonia in the blood, though some have suggested that it accumulates in the blood and its excretion in the urine is suppressed. 2. The ammonia excretion may be increased even to the extent of 2 gm. per day with an ammonia coefficient of 40 per cent., in conditions in which there is no acidosis.

An acidosis of high grade occurs in certain nephropathies. The acidosis reaches its maximum in the uremia of acute and of chronic diffuse nephropathy. It is not a terminal event, for it is often present in relatively high grade in outspoken cases many months before the development of uremia. It represents the effect rather than the cause of the renal lesions and thus constitutes a condition of only secondary importance. The characteristics of the chemical pathology of this acidosis are: 1. Increase in tolerance to bases. 2. Decrease in titratable alkalinity of the blood. 3. Decrease in the carbon dioxid content of the blood. 4. Normal excretion of ammonia. 5. Absence of any disturbance of carbohydrate or fat metabolism, and absence of the salts of any abnormal organic acids.

The changes in the titratable alkalinity of the blood which can be detected by the use of phenolphthalein afford a ready means for the prompt diagnosis of acidosis and the method is particularly applicable in renal disease. In this condition it furnished a definite indication of the amount of bicarbonate that will be required for the relief of the acidosis. The determination of the tolerance of the body to sodium bicarbonate also affords a delicate method of general application for the detection of acidosis. Examination of the feces showed that bicarbonate was not excreted into the intestine, even in the cases in which massive doses were injected. Some of the toxic symptoms of uremia Sellards claims are due not to the presence of a toxin, but to the absence of a normal constituent of the blood, namely, the carbonates. Therefore the therapeutic bleeding for the removal of any toxins that may be circulating causes at the same time a still further diminution in a substance in which the blood is already seriously depleted. This disadvantage could be readily obviated by the injection of bicarbonate at the time of bleeding. Sellards suggests that this acidosis is perhaps the result of defective function of the kidney in the normal separation and excretion of acid salts. If this supposition is correct, the acidosis would be an indirect expression of renal retention. In support of this it has been found that the acidosis is in general parallel to the ordinary signs of renal retention, such as the suppression of the excretion of dyes and sugars and the accumulation of non-protein nitrogen in the blood.

54 *Tuberculin Therapy in Tuberculosis Cutis, Tuberculides and Allied Conditions. G. M. MacKee, New York.

54. **Tuberculin Therapy in Tuberculosis.**—Fifty-two cases were treated by MacKee with bacillus emulsion in various dilutions. These cases included lupus vulgaris, tuberculosis, verrucosa cutis, tuberculosis of buccal mucosa, scrofuloderma, tuberculous adenitis, Bazin's disease, tuberculous dactylitis, papulonecrotic tuberculid and lupus erythematosus. In this series true tuberculosis of the skin apparently completely recovered under the influence of tuberculin injections. All the cases of ulcerative tuberculosis of the skin and mucous membrane failed to yield to tuberculin. At first this was thought to be due to the activity of complicating organisms, and perhaps it is, but these lesions failed to respond to a combination of tuberculin and mixed, polyvalent stock vaccines. The ulcerative lesions of Bazin's disease yielded at once. Lupus erythematosus and papulonecrotic tuberculid, which are thought to be due to the products of tubercle bacilli rather than to the organisms themselves, failed to respond. In this series of cases nothing but tuberculin was employed. There was no local or general treatment.

86 Biologic Treatment for Cancer. C. F. D'A. Francis, Brooklyn.

79. **Practical Management of Chronic Osteoarthritis.**—Roberts states in considering the treatment of osteoarthritis, the problem presented is to remove discernible foci of infection, improve local nutrition, correct such deformities as tend to put undue strain on weight-bearing joints, and to place the painful parts at rest, so far as that is possible. So-called anti-rheumatic remedies, such as the alkalies, salicylates and iodids, have no effect on these conditions and should be avoided because of the digestive disturbances which frequently follow their exhibition. The diet usually prescribed for "rheumatism" is harmful, because it denies certain elements of nutrition which the economy demands. Such treatment as is afforded at the various watering places is at best of merely temporary benefit and has at times been observed to be a source of real injury. Massage and manipulation of joints with the idea of keeping them pliable is an inexcusable error, for it serves only to perpetuate the irritation of the already sensitive tissues. It would seem, too, that the importance of correcting visceroptosis in these cases has been very much overestimated.

Where a focus of infection exists, it should be removed. Vaccine treatment offers much that is hopeful for the future, but it is still in the developmental stage. The essentials of treatment followed by Roberts in his cases have been the administration of glandular preparations, rest, a diet reducing the intake of calcium, and the use of the d'Arsonval or bipolar high frequency current.

82. **Ether-Oil Anesthesia.**—The advantages of the oil-ether outside of its simplicity in Luke's opinion seem to be more apparent than real. In fact, with the possible exception of selected cases of bronchoscopy, he finds it difficult to see any indication for its use that cannot be as well and probably more safely met by the modern pulmonary methods.

Some of the undesirable clinical features which, Luke says, must certainly be looked for in a method involving so many theoretical objections are the following: (1) the rather exhaustive and unpleasant experience accompanying any special rectal preparation, as required here; (2) the occasional necessity and inconvenience of preliminary and subsequent proctoscopic examinations, as a matter of safety and caution; (3) occurrence during the induction period of cramps, with distressing sensations of fulness and pressure in the lower bowel, accompanied by desire for stool; varying degrees of anal irritation occurring early or late; (4) prolonged induction stage with frequent necessary recourse to the inhalation method; (5) any time after the first fifteen or twenty minutes' respiratory depression may rather suddenly or slowly appear, followed by arrested breathing, loss of muscular tone and dilated pupils, with the possibility of fatal syncope supervening; (6) the occurrence of mild to very severe grades of proctitis and colitis, these complications appearing in more aggravated forms where any pre-existent pathological condition is present; (7) delayed recovery, which may be prolonged for many hours; (8) increased toxemia.

87. **Tuberculous Lesions.**—It is not right, says Pottenger, to speak of the tuberculin treatment of tuberculosis. Tuberculin alone is no treatment for tuberculosis. He considers the scientific treatment of tuberculosis a combination of tuberculin with all measures which will build up the patient and make his resisting power greater. The injecting of tuberculin alone, without proper care and supervision of the patient is unscientific and nothing short of malpractice.

Tuberculin is a specific remedy. Its action in tuberculosis is specific in that it stimulates the body cells to the production of certain definite antibodies whose function it is to attack and destroy tubercle bacilli and their toxins with which they come in contact. This is the only form of treatment that is specific. Fresh air, good food, proper regulation of life and the alleviation of distressing symptoms and complications are not specific, yet they are a very important part in the treatment of tuberculosis. They make the patient stronger; build up his resisting power; increase his reactivity and make his body cells capable of reacting to the tuberculin when it is injected or when it is produced normally.

Tuberculin also acts in stimulating healing. It increases fibrosis and aids in the production of scar tissue and encapsulation. While of inestimable value when properly given, it is of little or no value and may even do harm when given improperly. Too much must not be expected from tuberculin as a remedy. If it stimulates the body cells to the production of antibodies and increases fibrosis it is performing its function. It may fail to cure the disease and yet perform its function perfectly. Many men who use tuberculin fail to grasp what it should do. The result is that they are often disappointed. It cannot prevent necrosis when begun; it cannot fill up cavities; neither can it restore lost function to the various organs; but, if given properly, it will increase the antibodies in the blood, and will stimulate an increase of scar-tissue formation and thus improve the patient's chances of cure; but it should always be reinforced with other measures which will help the patient.

104. **Removal of Colon for Obstructive Fecal Stasis.**—Clark is skeptical as to the final outcome in cases in which the colon is not at least partially obstructed, for he cannot accept the theory that the colon is a useless organ. His experience convinces him that if the most conservative methods are adhered to, benefit may accrue from surgical intervention in these cases, but even with these successes there will be a considerable percentage of failures. A summary of his eight cases of colectomy shows the following results: 1. The radical relief of constipation in 5 of the 8 cases. 2. An absence of thirst in all but 1 case, and in this only of moderate degree. 3. An absence of immediate postoperative diarrhea in all cases, this symptom appearing several months later in one patient. 4. A somewhat remarkable gain in weight in 5 cases. 5. Striking improvement in general health in 3 cases with a considerable disappearance of neurasthenic symptoms; only partial or doubtful improvement in 2 and complete failure in 2; death of another from postoperative adhesions some months later. Although the immediate results were all favorable, yet the subsequent history Clark says may prove disappointing; therefore, it behooves every one who performs even a small number of these operations to keep the closest possible oversight of these patients after they leave the hospital. The most critical judgment should be brought to bear in analyzing results, for if it lead into wrong channels, this question has the greatest potentialities for surgical evil, and no one should report a single case without the fullest history and complete notes on the result some months subsequent to the operation. Based on practical deductions secured from the study of cases of general ptosis, Clark does not consider that they come within the operative domain unless obstructive symptoms are evident. For this reason, he does not deal with the ptosis *per se*, but with the particular portion of the intestine which is so hampered by actual sharp angulation that the fecal current is dammed back or retarded; hence the symptom of localized obstruction, rather than that of constipation, which cannot be relieved therapeutically, becomes the indication for surgical intervention. That his attitude is a conservative one is attested by the fact that in two years he has seen only eight cases to which he considered these radical measures applicable. These cases were represented clinically by extreme degrees of obstructive constipation, and dilated.

129 *Case of Trichiniasis with Unusual Blood-Picture. H. E. Cooper, Wauwatosa.

129. **Trichiniasis with Unusual Blood-Picture.**—A count of the leukocytes was made in Cooper's case on the day of entrance and showed 23,500 leukocytes. A smear of this blood was then stained with the Nocht-Jenner stain and a differential count of this stained specimen gave these surprising figures: Polymorphonuclear neutrophils, 18 per cent.; polymorphonuclear eosinophils, 72 per cent.; polymorphonuclear basophils, 0.5 per cent.; small lymphocytes, 1.5 per cent.; large lymphocytes, 1.5 per cent.; transitional leukocytes, 4.5 per cent.; large mononuclear leukocytes, 2 per cent. Other stains were made to verify this count, one of these stains showing an eosinophilia of 80 per cent. The attack was of slight intensity. The fever was intermittent in character, reached 102 to 103 F. in the afternoon, dropping down to normal in the early morning. There was no increase in pulse or respiration. The diarrhea which was present at the time of admission was checked within two or thrre days after entrance. The adult parasite, *Trichinella spiralis*, was never found in the stools. One week after entrance the fever began to decrease and on the tenth day was practically gone. The amount of eosinophilia remained about the same until several days after the temperature had become normal, when the count showed the eosinophilia to be decreased to 55 per cent. Just before leaving the hospital, apparently recovered, another count was made, which still showed an eosinophilia of 40 per cent., the picture being as follows: Polymorphonuclear eosinophils, 40 per cent.; polymorphonuclear neutrophils, 37 per cent.; polymorphonuclear basophils, 1 per cent.; small lymphocytes, 13 per cent.; large lymphocytes, 4 per cent.; transitional leukocytes, 5 per cent.

15 Mutilation of Wounded on Battlefield. J. B. Christopherson.

3. **Attempts to Find Disease Germs in Bed Bugs.**—Four hundred and fifty-five bed bugs were used by Thomson in this research, of which 184 were controls. No acid-fast bacilli were found in 105 bed bugs fed on lepers, nor in thirty-five bed bugs caught on the bed mattresses of leper patients. In the few experiments conducted, nothing abnormal was found in bugs fed on cases of lymphadenoma, chronic lymphatic leukemia, sarcoma, carcinoma and malaria. Forty bed bugs fed on a case of splenomedullary leukemia all developed numerous Charcot-Leyden crystals in their intestines.

6. **So-Called Cure for Trypanosomiasis.**—Yorke and Blacklock tested the "sera" (Mehnarto contratoxin) supplied by a Mr. H. C. Sieg and found that it had not the slightest

therapeutic value in animals experimentally infected with pathogenic trypanosomes.

7. Antimony Trioxid in Treatment of Trypanosomiasis.—As regards the amount of antimony trioxid which can be given at a single dose without causing toxic effects, either local or general, it was found by Yorke and Blacklock that, as is generally the case, a relatively much larger quantity is borne by small than by large animals. At least 1 mg. per 10 gm. of body-weight can be administered intramuscularly, or intraperitoneally to rabbits, guinea-pigs, rats and mice without any untoward result. In donkeys and dogs, on the other hand, such a dose frequently caused death, and even much smaller doses were followed by abscesses at the site of inoculation. Although the amount of drug administered can be regulated, there is no control over the amount or rate of absorption. Post-mortem evidence proves that the proportion absorbed during a period of six months is exceedingly small. In view of the extremely long periods after which relapses have occurred, the authors are cautious in stating that an animal is cured. But as several have remained negative without relapse for over two hundred days, and subinoculated animals have not become infected, it appears that a certain number of cures have resulted.

11. Development of Gametes in Malignant Tertian Malaria.—Thomson claims that crescents are produced from ordinary asexual spores of *P. falciparum,* due to a development of immunity toward the latter. They develop somewhere in the internal organs, and then appear suddenly in the peripheral blood. The period required for their development is about ten days. Crescents do not generally live more than a few days in the peripheral blood. Crescents may be present in the peripheral blood during periods as long as eight weeks, not because individual crescents survive for that time, but because their numbers are constantly replenished from surviving asexual forms. Fresh broods of crescents come into the circulating blood daily or every other day, or irregularly, according as the asexual sporulations occurring ten days before, were quotidian, tertian or irregular.

Quinin has no direct destructive action on crescents, either during their development or afterward, but it destroys the asexual source of supply. Quinin in doses of 20 grains daily reduces the crescents to numbers less than one per cubic millimeter of blood within three weeks. The crescents obtained from autopsy smears of the inner organs take about ten days to develop into the adult state in the inner organs. They develop chiefly in the bone-marrow and in the spleen. The protoplasm of the crescent in all stages of development stains a faint greyish-blue often with a yellow tinge, in contrast to the deeper blue of the asexual schizonts. Adult crescents have been found in autopsy smears of the spleen and bone-marrow after eleven days' quinin treatment (45 grains daily). Malarial pigment has been found in spleen and marrow smears after forty-seven days' quinin treatment (30 grains daily).

No evidence was obtained of parthenogenesis in crescents. Crescents become spherical in about four minutes after the blood is drawn, which appears to coincide with the time of coagulation. They may flagellate in four minutes after the blood is drawn, but some may not flagellate till after fifty minutes. The crescents in patients subjected to thorough and continuous quinin treatment are able to flagellate. The spherulation of crescents is probably due to osmosis, which in turn probably stimulates the actual flagellation. The polar bodies seen in crescents which have become spherical are extruded chromatin. The microgametocytes are capable of extruding 4, 6, 8 or 10 flagella (microgametes). There is no reason to believe that crescents ever flagellate in the circulating blood of a patient.

14. New Malaria Parasite in Man.—The parasite studied by Stephens was found in the blood of an East Indian child. It is extremely ameboid. Thin processes often extend across the cell or occur as long tails to more or less ring-shaped bodies. These processes may be several in number, and may give the parasite most peculiar fantastic shapes like that of an irregular web or mesh. The cytoplasm is always scanty, i. e., the individual ameboid processes are delicate or thin, and the parasite has but little bulk or density. While forms resembling "rings" do occur, yet, owing to the abundance of all kinds of irregular forms, it is certainly difficult to find quite typical "signet" rings.

Laterally applied parasites also occur, but in them the chromatin is not dot-like, as it usually is in the malignant tertian, but practically always rod-like. The nuclear chromatin is out of proportion to the volume of the parasite. It takes the form of bars or rods, strands, curves, forks, patches, etc.; the occurrence of the chromatin in a dot, as in the "ring" forms of other species, is rare. In the web-like protoplasmic processes mentioned above there may be seen several chromatin strands, and not uncommonly one observes a minute dot of chromatin some way from the parasite, or between two portions of the parasite, though the protoplasmic process connecting it with the main mass or masses is so thin as to be invisible. The chromatin masses are frequently angular, the angles jutting into the points at which an ameboid process is given off. Abundance of, and marked irregularity in distribution of, the chromatin masses are characteristic of this parasite.

20. Congenital Elevation of Scapula.—The chief features of the series of 18 cases of congenital elevation of the scapula analyzed by Fairbank may be summarized as follows: The sex of 8 was male, of 10 female. The right scapula was affected in 6 cases, the left in 9, while in 3 the deformity was bilateral. The scapula was anchored to the spine in 7 cases; in 2 of these, both scapulae were fixed, in one by a bridge of bone on both sides, and in the other by bone on the right and fibrous tissue on the left. Scoliosis was present in 10. In at least 4 a wedge-shaped half vertebra was present. In one of these, at the age of 2 years, there was no curve, but by 6 years a low dorsal curve, toward or rather below the elevated scapula, and quite unconnected with the half vertebra, had developed. In 5 the dorsal convexity was directed toward the raised shoulder, in 4 away from it, while in 1 case with an abrupt curve, both scapulae were elevated.

Partial fusion of ribs was seen in 7 cases, one of these being open to doubt. An unmistakable cervical rib was present in 2 cases only. In 2 there was total suppression of one or more vertebrae while in 4 cases, including the two just mentioned, there was present a half or wedge-shaped vertebra.

In 3 other cases the shortness of the neck made suppression of vertebrae more than probable, but the difficulties encountered in taking roentgenograms prevented a definite decision being arrived at. In 2 cases a projection or exostosis was present at the vertebral border of the scapula. With regard to other deformities present, 3 cases displayed torticollis, 2 of them having both scapulae elevated. The radius was absent in 1, the pectoral muscles were imperfect in 2, and facial asymmetry was noted in 2, only one of which was associated with torticollis.

21. **Severe Unilateral Hematuria.**—The control of the renal circulation during section of the kidney is obtained by Barling, by clamping the pedicle with rubber-covered forceps and placing several mattress sutures in the capsule, tightening them all simultaneously to take the strain off any individual suture and then tying them. When this has been done the clamp is removed and the kidney quickly replaced and compressed firmly inside the wound for several minutes with the hand over gauze pads; this Barling has generally found effective in stopping the bleeding.

23. **Traumatic Sensory Aphasia.**—According to Cope traumatic sensory aphasia is often, if not generally, due to subdural hemorrhage pressing on the cortical sensory speech centers. The aphasia affects the visual more than the auditory speech center. If treated expectantly, recovery is generally incomplete, and there is a risk of epileptiform convulsions developing later. Treatment by trephining and removal of the clot is the best course.

24. **Typhoid Spine.**—In 1909 Halpenny reviewed 72 cases of typhoid spine reported in the literature up to December, 1908. To this the authors add 20 cases reported since that time. These, with the 2 now cited, make 94 in all. A study of the cases since 1908 reveals the fact that when treatment is commenced early, spinal deformity rarely occurs, convalescense is short and recovery is nearly complete—that is, the movements of the spine approach more nearly to the normal.

27. **Excision of Diaphysis of Humerus.**—A female child, aged 5, was admitted to the hospital on Jan. 21, 1913. A week before admission she had fallen down-stairs, injuring her right arm. The case presented the obvious features of severe acute osteomyelitis involving the entire diaphysis. An incision was at once made down to the humerus and pus evacuated. The general condition of the patient was very critical at the time of admission, and therefore nothing more was done beyond employing free drainage. The local infective process appeared to have attacked both epiphyseal ends of the diaphysis simultaneously, the infection rapidly spreading up and down the bone.

March 3, 1913, the patient's general condition having improved, an incision was made through the deltoid muscle down to the bone, the shaft of which was found to be devoid of periosteum and surrounded by an irregular "involucrum" of new bone. The whole shaft, consisting of sequestrum and involucrum, was then withdrawn through the upper wound. The arm now consisted of nothing more than a flaccid tube of periosteum and granulation tissue, surrounded by the soft parts. It was placed in a specially moulded poroplastic splint fixed above to the axilla and below to the forearm at the elbow, the limb being so fixed that the muscles of the arm were fully extended and no contraction could take place. Drainage was provided above and below. The subsequent course of the convalescence was uneventful. Roentgenographic records, taken at regular intervals showed regeneration of bone taking place very rapidly along the whole length of the periosteal tube, the growth appearing as rapidly in the center of the limb as at its epiphyseal ends.

Twelve months after operation, the mobility of the shoulder and elbow-joint is unimpaired; full flexion and extension are present in the latter, while the movements at the shoulder are free in every direction. The right arm is shorter than the left to the extent of ⅝ inch; it is as strong and flexible as the other. The child can accomplish any sort of gymnastic exercise without pain or loss of power. The cosmetic result is excellent, the contour of the limb perfect, and the slight amount of shortening is difficult to detect, the healed scars being the only observable blemish.

29. **Acute Intestinal Obstruction.**—Four cases are reported by Marnoch. The first was caused by a volvulus of the cecum, the second by repeated operation for obstructive attacks due to congenital abdominal abnormalities; the third by an intersigmoid hernia and the fourth by a hernia into the paraduodenal fossa.

34. **Value of Gases Introduced into Pleural Cavity.**—Oxygen replacement according to Davies is not only of great value as a method of removing pleural effusions and exposing the lung for radiographic purposes, but it is the only efficient means we possess for the treatment of chronic cases of tuberculous pyopneumothorax. It is possible in these cases, by replacing the gas and fluid by oxygen, gradually to draw out the lung without producing any symptoms of distress or discomfort. The process must be repeated on three, four or even five occasions at intervals of two or three weeks, leaving on each occasion an increasingly high negative pressure. If the lung is completely fixed by adhesions, it cannot be made to reexpand, but it will be found that the tendency for the fluid (at first pus, and then serum) to reaccumulate will rapidly diminish—a state of affairs which is greatly appreciated by the sufferer.

35. **Need for Research in Antenatal Pathology.**—Routh urges obstetricians to look on research into antenatal pathology as only one of the methods which must be advocated in order to deal with statistics, and with the supply of material for research and for help in the diagnosis, prophylaxis and treatment of antenatal diseases, for without associated methods any large reduction of the antenatal death-rate is impossible.

55. **Drainage Tube in Abdominal Surgery.**—Owing to the adhesions which rapidly form around drainage tubes Adams claims their value is distinctly limited in the treatment of peritoneal infections. Since the tissues of the abdominal wall possess a much lower degree of resistance than the peritoneum, drainage of the former may frequently be called for where drainage of the peritoneum is not necessary. The presence and pressure of a drainage tube in peritonitis may determine the transudation of organisms from the lumen of the gut to the peritoneal cavity. This secondary infection is of less serious importance than might be supposed owing to the fact that the wound area has usually been shut off by surrounding adhesions before this occurs. To prevent adhesions between drainage tubes and adjacent structures the tube should always be rotated whenever the dressing is done, and its gradual withdrawal from the wound should be begun from the third day after operation. Gauze drains, Adams believes, are more properly termed gauze dams, except when used in the form of a small wick down the lumen of a tube as a "cigarette drain," and there the capillary action of the gauze may be of value in securing the escape of thin inflammatory fluid. In the case of thick pus they more often act as a cork at the orifice of the wound than as an external drain.

57. **Vaccination against Hay-Fever.**—Hay-fever treatment by active immunization with a pollen vaccine whether judged by statistics or by the experiential method, Freeman says, has succeeded, and the immunity thus acquired seems to last for one year at least after treatment has been discontinued.

64 Direct Sunlight in Treatment of Internal Diseases. (Héliotherapie.) Delachaux.

63. **Prophylaxis and Treatment of Functional Heart Disturbance in Children.**—Nobécourt emphasizes the importance of the injury liable to be felt by the cardiovascular apparatus from a too sedentary life, unhygienic attitudes in school and overstudy. Sitting still too long and lack of exercise increase the work of the heart as they reduce the activity of the peripheral circulation, while contributing to constipation, anemia and dyspepsia, all of which in turn react on the heart. Mild muscular exercise counteracts all these, but if the exercise is excessive or too long continued the children suffer equally from the other extreme. The circulation in children adapts itself with extreme facility to variations in movement, but prolonged effort is impossible and especially injurious if persisted in. Walking, to be a useful exercise, should be brisk and kept up for some time. It is not always good for children, and often entails a more or less durable dilatation of the heart. Games and sports should not be allowed to become competitive battles.

Gymnastic exercises are often directly injurious; the holding of the breath retards the circulation and fosters congestion. Swedish gymnastic exercises affect the circulation favorably but children find them tedious. Mental work dilates the carotid arteries; the heart-beat is liable to become accelerated, and the radial pulse smaller while the blood-pressure rises. He adds that when there is already some functional heart disturbance, there is still greater need to supervise the physical exercise, graduating it to the special case, as the main therapeutic reliance, supplemented by hydrotherapeutic measures, massage, care in the diet and measures to soothe the nervous system, respiratory exercises, etc. Abnormal excitability of the heart may be combated by valerian and belladonna, alternating each for twenty days. Or atropin can be given in the daily dose of a tenth of a milligram for each year of age. This is especially useful in paroxysmal tachycardia.

74 *Action of Antirennin on the Digestibility of Milk. L. Gaucher.

67. **Serotherapy of Acute Poliomyelitis.**—Netter makes intraspinal injections of the serum from persons who have had poliomyelitis at some time in the past, assuming that the serum contains antibodies which will have a therapeutic action. In one case reported an athletic man of 34 developed severe acute poliomyelitis but was apparently recovering when the eighth day his legs became paralyzed, with retention of urine and loss of sensibility up to the costal arch, all showing a progressive course, with an extremely serious outlook. The next morning 7 c.c. of serum from a person who had had poliomyelitis seven years before were injected into the spinal cavity. By this time the anesthesia reached to the nipples, but by evening of the same day the patient could "feel his toes," and complete recovery gradually followed. He was given ten injections in eleven days, a total of 66 c.c. The serum came from eight persons. Netter has applied this treatment before in four other cases, but with such timid technic and so few injections that although marked benefit was apparent each time yet some paralysis was left or the patients succumbed sooner or later.

72. **Alternating Hot and Cold Bath.**—Dausset and Hanriot recorded the blood-pressure, etc., in a healthy person in a warm bath; then hot water was added to bring the water to 42 or 50 C. After one or two minutes of this, cold water was added until the temperature was felt too cold. The vascular system is exercised to a remarkable extent by these temperature changes in the twenty-minute bath, but the changes are so gradual that there is no sudden shock. They say that oxidation processes are promoted, heat production is regulated, and sluggish elimination whipped up while the reflexes are brought back into physiologic limits.

82 Tuberculosis Primary in the Child; Reinfection in the Adult. (Les étapes de la bacillose de Koch chez l'homme.) L. Bernard.

80. **Vertebral Exostoses.**—Le Damany remarks that these excrescences are comparatively frequent; Regnault found them on sixteen of sixty-three cadavers examined, but as they usually grow outward they cause no nervous disturbances. In a case of his own, however, roentgenoscopy showed that the growth was compressing the cauda equina, explaining the clinical picture. The symptoms in these cases come on extremely gradually, and after removal of the growth they retrogress nearly as slowly. In his case months elapsed before the symptoms subsided, but this rendered all the more remarkable the fine result finally realized. The first symptoms had been pain in the legs which had been ascribed to and treated as sciatica without benefit. The man was given a course of treatment for syphilis, although the Wassermann test was constantly negative. By the end of the year the pains and motor disturbances indicated plainly pressure on the cauda equina, and the exuberant bone growth was removed by resection of the posterior arches of the third and fourth lumbar vertebrae.

85 *Articular Rheumatism and Endocarditis of Puerperal Origin; Recovery after Curetting. L. Pierra.

83. **Ovariectomy for Hemorrhage from Myomas.**—De Rouville has removed the ovaries for this cause in seven cases, *the hemorrhages for which the fibromyomas were responsible* being extremely severe and the patients too anemic to stand hysterectomy. The bleeding stopped at once after the castration. There was no recurrence except very slight in one case.

85. **Articular Rheumatism of Puerperal Origin.**—The case reported by Pierra shows anew how infection originating in the genital organs may work insidiously for several months before making itself apparent. It demonstrated further that a cure may be realized even at this late stage by eradicating the focus. His patient was a woman of 28 who developed subacute articular rheumatism and endocarditis five months after an infected abortion. No benefit was realized from a month or more of the ordinary measures, including the salicylates, but after straightening and curetting the uterus the temperature dropped to normal and rapid recovery followed, except that signs of mild mitral insufficiency still persist to date. The patient has passed through a normal pregnancy since. Articular rheumatism of puerperal origin does not attack so many joints as ordinary articular rheumatism. It generally settles down in one joint after a time—the shoulder in his case—and stays there. The rapid development of the mitral insufficiency in this case could be explained only by the slumbering infectious process in the uterus.

90. **Importance of Subjective Factors in Eating.**—Sternberg has long been preaching that food is liable to fail of its chief purposes unless it appeals to the senses of sight, smell and taste, with variety in the mode of preparation, appetizing seasoning and the dishes freshly prepared. He thinks that much of what we are now calling "vitamins" is included in the above. He has long been reiterating that the housekeeper's main dietary task is to cultivate the subjective factors, but as a rule this is disregarded as of little moment. He insists that our senses of smell and taste recognize chemical changes more sensitively than we can detect them with chemical tests. Warmed-over dishes, especially vegetables, do not relish as at first; some chemical change has occurred in them. This change has rendered them less wholesome for the person who finds them less palatable. Loss of appetite, disgust, nausea, vomiting and finally some dietary deficiency disease, form the sequence, and loss of relish should warn that we have entered on the downward slope. Sternberg emphasizes anew that the science of cooking is far more than merely applied chemistry and physics and application of heat. It is rather applied physiology of the senses, applied esthetics and applied psychology. It is a matter of taste in the widest sense of the term.

94 Gold Cantharidin and Tuberculosis. T. Spiess and A. Feldt.
95 *Protest against Newspaper Misstatement Regarding Friedmann Treatment. Pischinger, Ritter and Schellenberg.

93. **Development of Pulmonary Tuberculosis.**—Nicol's long article is accompanied with thirteen plates, one colored, ten illustrations in the text and a chart proposing a more accurate system of nomenclature, based on his research here reported. It has demonstrated, he says, that the tuberculous process in the lung spreads from above downward, and that the outlook is more unfavorable the lower its location.

95. **Protest.**—The officers of the German association of sanatorium physicians (Vereinigung der Lungenheilanstaltsärzte) here repeat their official protest against misleading statements in the lay press in regard to their attitude toward Friedmann's remedy for tuberculosis. They state that at their recent annual meeting at Berlin about half of the members went in a body to Friedmann's quarters to inquire about his remedy and see its mode of use. Few had used the remedy and they only on a very limited scale, and after their call on Friedmann many expressed great doubt in regard to the "success" claimed by Friedmann. An exaggerated account of the call appeared at once in some American papers, claiming that the entire association had visited Friedmann, that the members had reported treatment of 40,000 patients with the remedy, and that the results were phenomenal, the association tendering Friedmann a banquet—none of which they reiterate is true. (See The Journal, April 18, 1914, p. 1273.)

108. **Stasis in the Kidneys and Infection.**—Harttung threw a ligature around a rabbit ureter and studied the changes which followed in the kidney above. Staphylococci injected intravenously passed through the sound kidney without apparently injuring it, but in the kidney with ligated ureter severe lesions developed in all. *The stasis in the kidney* injures its tissues so that they become abnormally permeable for bacteria.

110. ***Lack or Excess of Iodin as Factor in Thyroid Diseases.***—Grumme presents arguments to sustain the view that a lack of metabolized iodin is the cause of myxedema, while exophthalmic goiter is the result of an excess of nonmetabolized iodin. In other words, the primary cause of myxedema is a deficiency of iodin in the food, while the cause of exophthalmic goiter is a functionally weak thyroid with a sufficiency or an excess of iodin in the food. Experience has already demonstrated that cretinism, myxedema and endemic goiter are favorably influenced by administration of organic thyroid-iodin or thyroid extract. On the other hand, iodin in any form, organic or inorganic, or food containing iodin, is distinctly injurious in exophthalmic goiter, and also in ordinary goiter, not of the endemic type, but which is often a preliminary phase of exophthalmic goiter. Endemic goiter can thus be effectively treated with iodin but it is strictly contra-indicated in the sporadic form outside of the mountains.

114. **Acute Threatening Conditions in Tropical Diseases.**—Mühlens emphasizes that we have now in salvarsan a powerful aid in combating relapsing fever. Given in time the severe symptoms subside at one stroke. He says that the confidence in salvarsan is now so great that in research at Tunis men deliberately inoculated themselves with relapsing fever by means of infected lice, the disease being promptly aborted with salvarsan as soon as it developed. He advises an intravenous dose of from 0.2 to 0.5 gm. according to age. One injection is generally enough to prevent recurrence, but a second, six or eight days later, will clinch the matter. When salvarsan or neosalvarsan is not available, symptomatic measures must be the reliance. Stimulants and saline infusion may be urgently needed at the beginning of the crisis on account of the danger of heart failure. He warns further that in the second stage of sleeping sickness, the patient must be constantly supervised on account of the tendency to suicide or homicide.

118. ***Non-Operative Treatment of Cancer.***—The Freiburg clinic seems to have carried radiotherapy of cancer farther than has been done elsewhere, and this communication analyzes *the experiences from the clinical, experimental and* physical standpoints. The best results were always obtained when the dosage was as large as possible and crowded into the shortest possible time. It is thus possible to induce the complete retrogression of deep-seated cancers without noticeable injury of sound tissue, and in some cases two years have elapsed without sign of recurrence. Krönig and his coworkers prefer the radiotherapy even for operable cases if conditions permit effectual cross-fire application of the Roentgen or mesothorium rays. Time alone will decide whether the tendency to recurrence is greater or less with radiotherapy. They insist that after operative removal of a cancer the region should be exposed to the rays at regular intervals for two years at least.

120. **Influence of Iodin on Non-Syphilitic Arteriosclerosis.**—Schwalbe sent a question-blank to a number of leading German clinicians to inquire their views on and experience with iodin in treatment of arteriosclerosis. He summarizes their answers, commenting on the wide divergence of ideas and technics, and emphasizing that none seemed to have a scientific basis for the use of iodin in arteriosclerosis. On the other hand, there seem to be so many drawbacks to the method, so much danger of injury from the iodin, especially in regions where goiter is common, that he sums up his conclusions in a solemn warning against the routine use of iodin or iodids in non-syphilitic arteriosclerosis.

123-125. ***Friedmann's Remedy for Tuberculosis.***—Here are the five articles relating experiences with this remedy which were summarized from advance sheets in the Berlin Letter, dated April 16. Biermann says he found the contents of the ampules contaminated with apparently pyogenic germs but they did not prove pathogenic when animals were inoculated with them. L. Brauer's impressions of the remedy were decidedly unfavorable, severe reactions being observed, and he knows of one person in Germany and two in Switzerland who died in a few days after the *injection with its severe* reaction. One of Hegler's patients had a chill, fever and extreme prostration after the injection, rapidly wasting *away after it and dying in six weeks.* Brauer reiterates that nothing was observed to indicate a favorable influence from the treatment, while the contamination with other microbes *renders this method of treatment a hazardous experiment.* Gaugele and Schüssler analyze their experiences with thirty-four children. One child died of miliary tuberculosis, and they say that the end seemed to have been hastened by the remedy. In 21 cases there was much suppuration, with high fever, and in 13 cases considerable infiltration but no actual abscess. They add that since the abscesses have healed the general condition seems improved. The children's appetite is better than before the injections, but no change can be detected with roentgenoscopy of the bone and joint processes and there has been no modification in the reaction to the tuberculin tests. A. Brauer reports the intramuscular application of the remedy in lupus and states that benefit was apparent in every case and with all forms of lupus, but that the improvement lasted only for ten or fourteen days, in no instance longer than three weeks. After a few weeks of apparent inactivity the affection seemed to become aggravated. In none of the cases by the end of the sixth week was the condition so good as in the cases given the ordinary local treatment for the same length of time. He thinks that the lack of durable effectual action on the visible lupus lesions is an intimation that internal lesions are not liable to be affected any more favorably.

129. **After-Pain Following Operations Under Local Anesthesia.**—Schlesinger says that it is the amount of fluid rather than the anesthetic which causes the pain, and that it is liable to be more severe in dense and tightly stretched tissues, other things being equal. Different persons vary in their sensation of pain, but he advises against injecting any fluid into inflamed tissues as this is almost certain to entail severe after-pain. The unusual number of nerve terminals and the compact, tightly stretched tissues render the after-pain peculiarly intense and tenacious with operations on the finger and toes. The local anesthetic should be injected into the loose tissue at the base of and between the fingers. When this is not possible, the amount of fluid used should be reduced to the minimum. An operation on a dermoid in the cheek, or a furuncle on the arm, with no zone of inflammation around it, is scarcely liable to entail after-pain. When the nature of the tissues renders it probable, it is better to refrain from local anesthesia or else give some sedative beforehand.

132. **The Problem of Muscular Rheumatism.**—Schmidt is convinced that the majority of cases of pain in muscles and nerves are of infectious or toxic-infectious origin. He has been confirmed in this view by the frequent complete cure of old rebellious myalgia and neuralgia after removal of the tonsils or evacuation of an empyema. The sudden onset of lumbago or the like after an abrupt movement he explains as the injury from the toxin on the fibers strained by the movement. Muscular rheumatism is in reality merely a neuralgia of the sensory nerve fibers in the muscle. He found among fifty cases of sciatica that in 86 per cent. other muscles or nerve domains were painful, spontaneously or on pressure, as well as the sciatic domain. There was pain in the lumbar region in 54 per cent. and in the femoral nerve region in 22 per cent. The knee-jerk was lost in 16 per cent. As the legs are used so much more than the arms, the greater chance for overstrain explains the predilection of the so-called muscular rheumatism for the legs.

149 *Splenectomy for Blood Disease. H. Eppinger and E. Ranzi.

139. **Tetany after Parathyroidectomy.**—Tanberg succeeded in inducing chronic tetany in animals by removing some of the parathyroids; in some there was a period of several months of latency before the symptoms developed. A meat diet did not seem to influence the tetany but a milk diet had an unmistakably favorable action. Milk apparently contains substances which modify the tetany under these conditions. Benefit was likewise manifested on feeding beef parathyroid glands.

140. **Tuberculin Tests of Animals after Diagnostic Inoculation.**—As early as two weeks after inoculation of the guinea-pig with the suspected sputum or other material, the animal may react to a subcutaneous injection of tuberculin in case of positive findings. Intracutaneous injection of the tuberculin answers the same purpose although the findings are less objective. If a negative response is obtained, the procedure should be repeated a few days later to make sure.

142. **Leukocytosis with Intraperitoneal Hemorrhage.**—Hoessli found 30,000 leukocytes in a previously healthy young woman suddenly taken with symptoms suggesting rupture of a gravid tube, confirmed by immediate operation, with prompt recovery, the leukocytes numbering 8,000 the tenth day. Three similar cases are reported in which the leukocytes ran up to 15,000 or 19,000 in twenty-four hours after the first signs of trouble. Extra-uterine pregnancy was regarded as probable in all but one case in which the symptoms and intact hymen spoke for appendicitis, but the trouble proved to be a ruptured blood-cyst in the right ovary. Some experiments on animals confirmed the fact that sudden large influx of blood into the peritoneum is liable to induce high leukocytosis for about twenty-four hours, even in the absence of all inflammation.

143. **Coagulation-Promoting Substance.** — Blood-platelets from animals, obtained by fractioned centrifuging, sterilized by heat and desiccated, may be dissolved as needed and injected to arrest hemorrhage. This substance has been in use at Kocher's clinic for over a year and Fonio here analyzes the experience with it, showing that it answers the physiologic requirements better than any other method of arresting hemorrhage except transfusion of blood. It has the advantage over the latter that it supplies only the one element needed, and that the doses can be graduated. The method is still in the tentative stage. Various by-effects are observed showing that the best method of administration has not yet been worked out. The pulse and temperature ran up regularly after intravenous injection and sometimes there were pains in the heart region, dizziness, vasodilation in face and neck and headache. By administering part of the solution by subcutaneous injection, the by-effects were much reduced. The more blood the patient has already lost, the smaller the dose required.

144. **Gastric Ulcer.**—Kehrer recalls that pain in the stomach may be due merely to contraction of the muscle, and his experiments on dogs have demonstrated that the expulsion of the blood from the contracted portion of the muscle renders it defenseless against the corroding action of the gastric juice and erosion may occur with its sequel of ulceration. This is especially liable when the muscular contraction occurs predominantly in the pylorus region.

145. **Pathologic Anatomy of Exophthalmic Goiter.**—This fifty-four page article from Kocher's clinic reviews the findings in eight additional exophthalmic goiter cases, the patients from 22 to 49 years old. Three of the patients had died during an operation on the goiter and the others had died of intercurrent disease but of such mild nature that the exophthalmic goiter must be regarded as the actual

cause of death. Considering these cases with a previous series of four, he states that 80 per cent. of those who died in connection with the operation had an abnormally large thymus—a mixed hyperplasia—as also 66.6 per cent. of those succumbing to mild intercurrent disease. Thus the thymus was of normal size in 25 per cent. of the total material. Dilatation and hypertrophy of the heart was the rule, but in one of the severer cases the heart was of normal size. Both liver and kidneys showed fatty degeneration in all the cases, and the chromaffin system showed hypoplasia. The blood findings confirmed Kocher's typical blood-picture, the leukocytes ranging from 4,300 to 8,800; the neutrophils from 36.7 to 71 per cent. and the lymphocytes from 24.3 to 58.6 per cent. although three of these patients had no signs of the lymphatic status and two only slight indications of it. No connection was apparent between the lymphocytosis and persisting thymus.

147. **Ossifying Myositis.**—Gruber adds twelve more to the seven cases he has already published in which there was bone-production in muscle tissue. Some acute or chronic trauma seems indispensable for this chronic osteoplastic myopathy.

149. **Splenectomy in Blood-Diseases.**—The twenty-two cases on record are tabulated and compared and the remarkably favorable influence of the splenectomy is emphasized in the three types of blood disease represented by hemolytic jaundice, cirrhosis of both spleen and liver, and pernicious anemia. In cases of thrombophlebitic enlarged spleen, splenectomy seems to offer little chance for benefit unless one's hand is forced by severe hemorrhages in the gastro-intestinal canal.

154 Leishman's Anemia in Children at Palermo; 110 Cases. R. Jemma.
155 *Transmission of Scarlet Fever by Patients after Discharge from the Hospital. W. Knopfelmacher and R. Hahn.

151. **Latent Tuberculosis in Infants.**—Pathologic anatomists agree that latent tubercular foci are often found in children. Ossinin, in order to determine how frequent they are, examined the bodies of 100 children under 9 months of age. He examined the bronchial, tracheal and mesenteric lymph-nodes by treatment with antiformin, histologic examination and inoculation in guinea-pigs. In ninety-seven cases the results were negative by all three methods. In the other three cases, macroscopic and microscopic examination was negative and there had been no clinical symptoms of tuberculosis, but the antiformin examination and guinea-pig inoculation were positive. That is, there was latent tuberculosis in 3 per cent. of the cases. In all the cases it was in the bronchial and tracheal glands, and not in the mesenteric. This seems to confirm the belief that the respiratory tract is the chief portal of entry for tuberculosis.

155. **Prophylaxis of Return Cases of Scarlet Fever.**—A considerable number of scarlet fever patients after their discharge from the hospital infect other members of the family. The percentage varies according to different authors and in different epidemics from 3 to 10. This may be due to the fact that the patient still carries his own virus or that he acts as a carrier of infection from other patients with whom he has come in contact. Knopfelmacher and Hahn say that the latter would seem to be more generally true, as this form of infection is more frequent in hospital cases than in those treated at home. Therefore our quarantine regulations do not seem to be sufficient. The best thing would be to isolate all cases in separate rooms for twenty days; but this is costly and difficult to enforce. It is therefore recommended that after the disappearance of acute symptoms the patients be placed in a common convalescent room, but not allowed to come again into contact with acute cases.

167 *Treatment of Tuberculosis. (Zur Heilung der Tuberkulose.) Ponndorf. Commenced in No. 14.

167. **Tuberculin Treatment of Tuberculosis** —Ponndorf analyzes the experiences at Weimar with tuberculin treatment in 153 cases of various forms of tuberculosis: 44 were entirely cured; 37 much improved and 28 improved, while the outcome is not known in 12 cases; 13 showed signs of a reaction and the course of treatment was dropped. He mentions parenthetically that 37 of 59 patients under 25 had more or less of a tendency to goiter, and the thyroid returned to normal size in nearly all those who were benefited by the tuberculin treatment. The same treatment was applied to three diabetics without modifying the diet, and the sugar in their urine dropped from 6 to 2 per cent.; from 4.25 to 1.8; and from between 2 and 5 per cent. to zero after one or two sittings. He uses an amplified vaccination technic.

173 *Treatment of Cholera with Hypertonic Saline Infusion, Tincture of Iodin and Potassium Permanganate. O. Löwy.
174 Alimentary Galactosuria in Liver Disease. R. Fleckseder.

169. **Benzol in Leukemia.**—Spiegler's patient was a woman of 38 with myeloid leukemia. After two months of benzol treatment, she was much improved but returned five months later with extreme anemia, only 1,400 leukocytes, and multiple hemorrhages in skin and mucous membranes. At one count the leukocytes numbered only 400. Necropsy revealed signs of severe toxic injury of the parenchyma of various organs, especially marked in liver and kidneys. There was no manifest change in the spleen, but the granulated elements disappeared from the blood and lymphocytes took their place. Two similar cases have been published in which the leukocytes dropped under benzol from 988,000 to 1,720 and from 56,000 to 5,300 and later to 200. These experiences impress the necessity for vigilant and repeated control of the blood count as indispensable whenever benzol is being given.

173. **Cholera.**—Thirty-one cholera cases are described to emphasize the efficacy of treatment according to Rogers' method, restoring fluid by subcutaneous injection of 1.5 per cent. salt solution and giving the patients a very weak solution of potassium permanganate to drink copiously. Hot tea and black coffee were also given freely and three times a day ten drops of tincture of iodin. Three died of the eighteen patients treated systematically in this way, all very severe cases.

178 Postoperative Pseudomenstruation. E. Holländer.
179 Intestine Slips into Loop of Silk Formed as Ligature Loosens Up. (Seltene Form von Strangulation einer Darmschlinge.) R. Vogel.

175. **Preparing for an Operation on the Brain.**—Haberland remarks that shaving the hair preliminary to an operation on the brain is depressing to the patient, tedious for the operator, and liable to cut the skin. He has found that the hair comes off totally and easily in three minutes without the least trouble if barium sulphid (*Barium sulfuratum*) is applied to the region. In three minutes the hair can all be scraped off with a little stick. The only drawback is the odor, but this can be disguised. The hair soon grows out again. He mixes the sulphid with water to a thin paste, with or without addition of a little soap, and applies it with a brush or the hand. After the hairs have been scraped off he rinses and dries the region.

184 *Epinephrin Treatment of Osteomalacia. (Die Methode Bossi bei Osteomalakie.) D. Cavarzani.

182. **Necrobiotic Endometritis.**—Driessen says that he has encountered seventy-five cases of a peculiar endometritis which is liable to bring on profuse hemorrhages. He ascribes it to abnormal menstruation; the casting off of the mucosa does not occur as regularly as under normal conditions and necrotic scraps cling in place. Just as scraps left after abortion are liable to set up hemorrhage, so these scraps of mucosa may entail it, and the findings closely resemble those in the endometritis after abortion. He has encountered it in many cases in which the possibility of a pregnancy was out of the question. The women are usually approaching the menopause and the girls are passing through the stress of puberty. The abnormal features of the menstruation are thus easily understood. Curetting may cure completely, but as the process recurs at each menstruation the effect is only temporary. A permanent cure is generally possible only when the ovarian functioning, the remote cause, is either modified or stops completely. Either ovariectomy or roentgenotherapy may be considered for the purpose. The latter seems especially promising in these cases which deceptively suggest malignant disease, both clinically and under the microscope, by the necrosis, hyaline degeneration, proliferation of epithelium, tendency to cyst production and signs of inflammation.

184. **Epinephrin Treatment of Osteomalacia.**—Cavarzani adds another to the forty-six cases on record in which systematic epinephrin treatment cured osteomalacia. At the same time he cites twenty-six cases that have been reported in which little or no benefit was derived from the treatment. In some of these cases the epinephrin was stopped at the first sign of intolerance, so the treatment had really no chance to display any efficacy. The hypophysis seems to be able to sensitize the adrenals, and hence combining hypophysis extract with the epinephrin treatment might enhance the action of the latter, he suggests. He adds that there is much to sustain the assumption that deficient functioning of the adrenals interferes with the normal growth of the skeleton. His observation of the prevalence of rachitis and osteomalacia in regions with certain types of soil and drinking water has convinced him that a deficiency of lime in the food has something to do with their development.

187. **Iodin-Benzol for Sterilization of the Skin**—Zanetti has been testing various substances as vehicle for iodin, to take the place of the tincture which deteriorates so rapidly. He announces that benzol dissolves iodin readily and the solution keeps indefinitely, while the benzol seems to enable the iodin to penetrate deeper into the skin. The saturated benzol solution contains 9.75 per cent. iodin while the tincture represents less than this.

196 *Acute Hemorrhagic Pancreatitis. H. Bindslev.

196. **Acute Hemorrhagic Pancreatitis.**—Bindslev states that he encountered three cases of this affection in a recent six months' period, all in women between 52 and 67, and all fatal. All of them had had pain in the upper abdomen at times, ascribed to gall-stones, and gall-stones were found at the operation in every case. The pains were characteristic, not radiating, with pain-free intervals at first, but the pains increasing and becoming continuous in time, often so intense that even morphin did not relieve. Vomiting generally occurs early and often keeps up with surprising regularity. The collapse and violent pains may suggest perforation, but with perforation of the stomach the tenderness in the region is more intense and the board-like hardness of the abdominal wall differs in every respect from the peculiar meteorism with pancreatitis. The temperature usually runs up higher than with ileus. If there are no signs of thrombosis, endocarditis or phlebitis, pancreatitis seems more plausible than embolism when the signs of shock develop gradually, in the course of a day or so, and the temperature rises only gradually. There was a tendency to arteriosclerosis, obesity and cholelithiasis in the three cases reported, plus endocarditis in one case, but the biliary passages were not obstructed in any instance. The abdomen was opened in each case, but the conditions were found already irreparable.

THE ABDERHALDEN-FAUSER REACTION IN MENTAL DISEASES

WITH SPECIAL REFERENCE TO DEMENTIA PRAECOX *

CHARLES E. SIMON, B.A., M.D.
Professor of Clinical Pathology and Experimental Medicine at the College of Physicians and Surgeons of Baltimore
BALTIMORE

After Abderhalden had demonstrated that the animal organism responds to the parenteral introduction of alien proteins by the appearance in the blood of proteolytic ferments which are directed more or less specifically against the proteins in question, the thought naturally suggested itself that similar reaction products might also appear, if proteins derived from the animal's own body were to find their way into the circulation. Theoretically, this seemed not at all unlikely, since practically every cell that is not bathed directly in the blood-stream must, in a manner, be alien to that medium. As a matter of fact, Abderhalden could demonstrate that in pregnancy, during which chorionic cells are known to enter the maternal circulation, corresponding ferments do appear and remain demonstrable as long as pregnancy continues. A basis was thus established on which a multitude of biologic and hence of pathologic questions also became subject to experimental investigation, and among these, of course, the problem of the long-suspected connection between certain mental diseases and the functional activity (namely, derangement) of the sex glands. So thoroughly has this been appreciated that there is probably not a single psychiatric clinic of note where serologic studies of this order are not now in progress. The general interest in this direction has been further accentuated by the enthusiastic reports which have emanated from Fauser's clinic concerning the findings in the dementia praecox group, and it is with this question more especially that we are concerned in the present communication.

In his address before the annual meeting of the German Psychiatric Association, held in Breslau in May, 1913, Fauser[1] reported that he had then examined some 250 patients afflicted with various forms of mental diseases, and that he had found protective ferments directed against sex glands only in dementia praecox; that the serum of male patients reacted only with testicular antigen and the serum of female patients only with ovarian antigen.

As negative reactions alone were obtained in the other purely functional psychoses, such as manic-depressive, hysteric and purely degenerative insanity, etc., he very naturally concluded that the method might become of signal value in differentiating dementia praecox from these other types. In a footnote he adds that ferments of this order were later found also in isolated cases of patients who were at the time not (not yet?) suffering from dementia praecox; but that in these cases there was a demonstrable abnormality of function (dysfunction) on the part of the thyroid gland, and that clinically also these cases could readily be differentiated from the functional psychoses just mentioned.

Besides these findings in dementia praecox, Fauser also ascertained that ferments directed against brain cortex can be demonstrated in the majority of cases, while a reaction to thyroid tissue was only occasionally noted, though, at times, it was observed in the absence of any recognizable enlargement of the gland. In the purely functional psychoses other than dementia praecox, on the other hand, no antiorgan ferments of any kind could be demonstrated.

In contradistinction to these findings were those obtained in certain neuroses and psychoses associated with evident enlargement of the thyroid gland, in which the symptoms of the patient would in a general way have warranted the diagnosis of dementia praecox, and in which both cortex and thyroid were digested, but sex gland was not affected. In paresis also, ferments directed against cortex were almost invariably present, and occasionally ferments against liver and kidney, while those against sex gland could not be found.

Since Fauser's original reports, several other papers have appeared which deal with the same question and which in a general way confirm his findings, although the experience of some investigators has been less encouraging.

Wegener,[2] in a preliminary report covering 200 cases, and in a second communication in which the findings in 600 cases are detailed, confirmed Fauser's observations. In commenting on his hebephrenic cases he distinguishes between simple hebephrenia, hebephrenia associated with katatonia, and hebephrenia in which a definite mental deterioration had already occurred (dementia praecox). In the first group (121 cases) he observed cleavage of sex gland; in the second (12 cases), in addition to this, cleavage of thyroid, which never occurred in the first; and in the third (96 cases) cleavage of sex gland and cortex. Only negative results were obtained in simple "affect"

psychoses, simple hysteria and in chronic paranoia. In epilepsy (61 cases) a reaction with cortex was obtained immediately after the attack and in cases progressing to dementia also in the interval. In melancholia (25 cases) cleavage of liver was observed, and in some cases also of sex gland, but in the latter event the subsequent course of the malady showed that the melancholia had merely obscured the underlying psychosis, especially a hebephrenia. Cleavage of cortex was noted in chorea (6 cases), multiple sclerosis (8), arteriosclerosis cerebri and senile dementia (12), paresis, lues cerebri and tabes (67), brain and spinal tumors (15), meningitis (10), following narcosis and local anesthesia (8), alcoholic psychoses (8) and paralysis agitans (1). Summarizing his general impressions, Wegener refers to the evident importance of the reaction in the differential diagnosis between otherwise similar cases and to the unfavorable prognosis which those offer in which cortex cleavage can be demonstrated on repeated examination.

Kafka,[3] as the result of a study of 100 cases of mental diseases, concludes that ferments against sex gland are characteristic of dementia praecox, but adds that positive results may be exceptionally obtained also in paresis and during epileptic seizures. The sex-gland reaction, however, was not obtained in all cases of dementia praecox, and in full strength only in 13 out of 30, while 12 were entirely negative. The reaction with thyroid was positive in 20 of 38 cases, and it is interesting to note that the majority of the praecox cases in which the diagnosis was not self-evident on first examination, belonged to this order. A definite cortex reaction was found in 20 out of 32 cases, and one with adrenal tissue in 5 out of 22. Like Fauser, Kafka emphasizes both the diagnostic and the prognostic value of the method in the study of mental diseases.

Mayer[4] reports his findings in 47 cases of mental disease, and concludes from a study of 16 cases that in dementia praecox the serum always contains homologously directed ferments against sex gland, and that it usually also reacts with thyroid and cortex, while no ferments were found in the other functional psychoses. In paresis, on the other hand, he found a reaction with sex gland in 5 out of 8 cases, with cortex in all and with liver in 5.

Further confirmatory reports have been published by Fischer[5] of Stuttgart (24 cases), who found that in 12 dementia praecox cases a reaction occurred "fairly" constantly with cortex and sex gland, and in those which were complicated with thyroid hypertrophy, also with thyroid tissue. In his four cases of manic-depressive insanity, no tissue reactions were obtained, while a response to cortex was noted in all the paretics that were examined (15).

Römer and Bundschuh[6] of Illenau (36 cases) noted a reaction with cortex and testicle in 15 cases of dementia praecox, out of 20; with cortex and thyroid in one, with all three organs in 3 and with thyroid only in 1. Negative reactions were obtained in 6 normal persons and in 4 cases of manic-depressive insanity. In paresis (6 cases) a positive reaction with cortex exclusively was observed in 3, with cortex and thyroid in 1, with cortex and testicle in 1 and with testicle only in 1.

Theobald[7] reports a reaction with sex gland in 53 per cent., with cortex in 63 per cent., and with thyroid in 69 per cent. of the praecox cases. Fuchs and Freund[8] finally report a small series of cases (23) which were examined against sex gland and pancreas. Of the six manic-depressive cases some reacted with sex gland, while one gave a feeble reaction with pancreas. In this instance sugar had been found in the urine on two occasions. Of the 12 dementia praecox cases, 11 reacted with sex gland and all of them with pancreas, while a pancreatic reaction was noted in 5 paretic cases out of 7. Of the three male patients, one gave a full response to testicle, and of two female patients one reacted similarly to cow's ovary.[9]

Beyer[10] reports a positive reaction in six cases of dementia praecox (100 per cent.), and a negative reaction in two cases of manic-depressive insanity (100 per cent.) and one of paresis.

In contradistinction to the investigators above mentioned, Neue,[11] Allers,[12] Willige,[13] Hauptmann and Bumke,[14] and Brahm[15] have arrived at less encouraging results. Allers of Munich, however, seems to have confined his investigations to the behavior of the serum toward brain tissue. He concludes that even with a perfect technic positive reactions are at times obtained in circular insanity and the psychopathies.

Willige of Halle states that in paresis a reaction with brain tissue was observed in the majority of cases, but that in most of these the serum also reacted with thyroid and testicle. So far as the dementia praecox question is concerned, he merely mentions that in "isolated katatonic cases the reaction with brain tissue was negative." Two hypophyseal tumors gave a marked reaction with hypophysis; one also a feeble response to thyroid. One brain tumor reacted with thyroid, but not with brain.

Neue, working in Schröder's clinic (Greifswald), merely admits the more constant occurrence of positive reactions toward sex gland, cortex and thyroid in dementia praecox, as contrasted with degenerative cases, manic-depressive insanity and normal persons (positive reactions with testicle, pancreas and thyroid in seven out of nine young, healthy, male attendants). Of eight cases of paresis, cleavage of cortex was observed in all, but frequently also that of other organs (pancreas, liver and kidney). Seven cases of cerebral arteriosclerosis reacted with cortex and prostate and sometimes also with testicle.

The results of Hauptmann and Bumke (Freiburg) are altogether divergent from those of Fauser. The two former observers thus not only failed to demonstrate the homologous sex-gland specificity of the blood ferments which had been established by Fauser and confirmed by others, but also obtained sex-gland reactions in psychoses other than dementia praecox, in non-mental cases and in "normal" persons. Hauptmann adds, however, that he was able to convince himself in Fauser's laboratory of the validity of Fauser's claims and that specific reactions were there obtained even with tissues that had been prepared in Freiburg.

Brahm finally reports that cleavage of brain peptone was observed in all of his dementia praecox cases; that a corresponding reaction with silk peptone occurred in 50 per cent. of the cases; that serums from praecox cases frequently reacted with placenta; that in paresis the cleavage of brain antigen is feebler and that positive reactions also may be observed in psychopathic cases.

In surveying the literature just outlined, one cannot help being impressed, on the one hand, by the wonderful apparent uniformity of the results reported by Fauser, and on the other by the total lack of uniformity of those obtained by others, such as Hauptmann and Bumke. The thought naturally suggests itself that two factors may have been operative to this end, namely, that Fauser was carried away by his enthusiasm and allowed himself to be influenced unduly in the direction of his own wishes, and that Hauptmann and Bumke lacked complete control of the technic. As a matter of fact, there is good ground for the belief that both factors were operative. Fauser himself states that he obtained a reaction with sex gland repeatedly in cases in which this "was not expected or at least not certainly expected"; that in the cases in question, either the diagnosis between manic-depressive insanity and dementia praecox could not be made with certainty, or the diagnosis of manic-depressive insanity seemed to be the only diagnosis warrantable. He adds that in just such cases the serologic diagnosis proved superior to the clinical diagnosis, as evidenced by the subsequent course of the malady or the added information brought out by a more searching investigation into the patient's history. Fauser, in other words, admits that he tried to make his clinical diagnosis fit the serologic one in cases in which the two did not tally, rather than leave the question of the occurrence or nonoccurrence of the reaction in the functional psychoses open for the present. This, of course, can be readily understood, if we realize the enthusiasm which his discoveries must have elicited in his own mind; but, on the other hand, it seems that the time interval which elapsed between the serologic examination and the change in diagnosis was scarcely long enough to warrant this change.

Another factor which may properly be advanced against the immediate acceptance of Fauser's published results is his absolute silence regarding questions of technic, and the fact that his results seem to have been as uniform before Abderhalden himself realized the necessity of increasing his demands on the character of the technic, as afterward. As a matter of fact, there is probably not one worker in this difficult field who, even after a long familiarity with the work, has not failures to record in abundance. To be sure, Fauser says in his final response in connection with the discussion relative to his address at the meeting of the German Psychiatric Association in Breslau, that with his earliest tests he obtained results which were truly tragicomic, and remarks that even Abderhalden in his pregnancy work had similar experiences. Granted all this; but even so, one can but wonder at Fauser's uniform results after he had passed beyond the stage of tragicomedy to which he refers.

On the other hand, there can be no doubt that certain workers like Hauptmann and Bumke reported their findings at a time when they certainly did not control the necessary technic. The writers virtually acknowledge this, but it is certainly much to be regretted that workers who fail in their first attempt to confirm the findings of another, should rush into print, apparently prompted by the sole desire to contradict the findings of probably equally honest workers.

Whatever the reason, the results obtained by different observers, though they support the claims of Fauser in the main, are still sufficiently divergent to warrant the report of another series of observations such as our own. The material for these examinations was obtained from the Sheppard and Enoch Pratt Hospital, and comprises 106 cases. The serums were tested against sex gland, Basedow thyroid and cortex. The results will be seen in the accompanying table.

TABLE OF RESULTS IN 106 CASES TESTED AGAINST SEX GLAND, BASEDOW THYROID AND CORTEX

	No. of Cases	Sex Gland	Per Cent.	Basedow Thyroid	Per Cent.	Cortex	Per Cent.
Dementia praecox	25	22‡	88	13	56	10	40
General paresis	11	0	0	4	36	5	45
Manic-depressive insanity	25	4	16	9*	36	6	24
Involutional depression	10	2	20	5	50	4	40
Constitutional psychopathic states	4	2	50	4	100	4	100
Defective mental development	3	0	0	0	0	2	66
Toxic (nephritis) cases	2	2	100	0	0	1	50
Intoxication psychosis (alcohol)	5	4	80	1	20	1	20
Traumatic psychosis	1	0	0	1	100	0	0
Organic dementia	3	0	0	0	0	2	66
Exhaustion psychosis	1	0	0	0	0	0	0
Drug intoxication (morphin)	1	0	0	0	0	0	0
Doubtful diagnosis	15	10†	66	2	11	4	26

* All of these patients were agitated, showing "Angst" symptoms.

† All of these patients showed constitutional psychopathic tendencies.

‡ In three patients classed as having dementia praecox and who did not react, the disease was of several years' duration.

To summarize, we can say that a sex-gland reaction may be obtained in nearly, if not all, cases of dementia praecox at some stage of the disease, but that the reaction is not specific of dementia praecox, as Fauser would have us believe. It may, of course, be debatable whether the relatively small percentage of cases in which the clinical history pointed to manic-depressive insanity, but in which a reaction was obtained nevertheless, were in reality manic-depressive cases, but the fact remains that in other types of insanity the reaction may also be obtained, even though we admit that it is observed far less constantly. Of special interest is our observation that in a large percentage of alcoholic cases a sex-gland reaction seems to be obtainable. It will be noted that no reaction was obtained in any one of the eleven cases of paresis. Our results thus seem quite in accord with those of Fauser, but just as he notes that at one time one of his associates obtained a positive reaction in an isolated case of paresis, so also did Dr. Judd in another series of mental cases note a positive reaction in a few instances. The significance of these divergent findings may of course be manifold.

In this connection I would recall the observations of Lampé and his co-workers, Papazolu and Fuchs, who report that in Basedow cases a sex-gland reaction may be frequently observed. It might, of course, be argued that as no clinical histories are given in full, some of these may have been dementia-praecox cases, but as the report has emanated from the first medical clinic of Munich, it hardly seems likely that all the positive cases were of that order. Such apparently divergent findings, however, in no way diminish the basic importance of Fauser's original observations from the standpoint either of diagnosis or of general biology and experimental medicine. The fact remains that in dementia praecox a positive reaction is the rule, and that in the purely functional psychoses it is the exception. Its possible occurrence in paresis and alcoholic insanity scarcely diminishes the importance of the reaction from this point of view.

How to explain our positive findings in manic-depressive cases I do not know. It is possible that some of these cases were really praecox cases, but it is not likely that this explanation would be applicable to all our exceptions to the general rule of Fauser that in manic-depressive insanity only negative reactions are obtained. We must, hence, either conclude that Fauser's rule does have exceptions, or that our positive findings were due to some error of technic. Before admitting or denying this possibility, it may not be out of place to enter in some detail on the general question of technic.

TECHNIC

As I have previously indicated, Fauser does not discuss the question of technic at all, but merely states that he followed the rules of Abderhalden implicitly and that his results, before Abderhalden "reenforced" those originally laid down, were practically the same as afterward. These rules have reference essentially to the condition of the serum, to that of the parchment thimbles, and of the tissues which are used as antigens.

Concerning the first factor, he asserts that the serum must be free from hemoglobin or corpuscles and uncontaminated by bacteria. These demands were complied with in every particular. The blood was collected in large vacuum tubes similar to the smaller Keidel tube, which permit of thorough dry sterilization, and can be handled with equal facility. The blood was placed in the ice-box over night, the serum separated by centrifugation the next morning and recentrifuged twice more before being used. No serum was used that was tinged reddish in the slightest degree. The dialyzers which were available at first were those originally advocated by Abderhalden, namely, No. 579 Schleicher and Schüll. As a large percentage of these were found to be too pervious, the firm placed a tighter thimble on the market, bearing the number 579a. The first lot of a hundred of these were found so tight, however, that using only 0.5 c.c. of serum in each, no reactions could be obtained with sex gland unless the incubation was extended to from sixty to sixty-six hours. Subsequently, a lot of supposedly tested thimbles were secured from Schoep of Halle, but these also were found to be rather tight, necessitating incubation for sixty hours with 0.5 c.c. of serum. Quite a number of these, moreover, had to be discarded, as they were permeable to serum, in spite of their having been sent out as "tested."

All the thimbles were, of course, tested with serum alone, and those discarded which allowed reacting substances to pass through. If the dialysate gave no reaction with ninhydrin, they received a single notch in the margin, and were then tested against serum in combination with a tissue which was known to react readily, such as a very cellular carcinoma, which gave reactions with practically every serum whether derived from a normal person or a patient; while when placed in the dialyzer by itself, the dialysate gave no reaction whatever with ninhydrin. Or, the thimbles were tested with an "unimportant" organ in a series of experiments, and those selected which gave reactions in the dialysate. Either procedure gives the same results as when tested with peptone alone. After having been shown to be permeable for substances resulting from the interaction of serum and tissue, the thimbles received two additional notches and were then set aside in jars under toluene until needed for an actual experiment. Early in our work we sterilized our dialyzing jars with the dialyzer and the necessary amount of water, in the steam sterilizer, before using them, but abandoned this when it was found that the permeability of the thimbles was thereby lessened.

After being used the thimbles were carefully washed under the tap, placed in jars under running water for several hours and then stored under water and toluene until needed. The average life of a thimble under such conditions, being in use for from three to four days of every week, certainly extends over several months.

I have pointed out above that in most of our experiments we used but 0.5 c.c. of serum to each thimble. We may be criticized on this point, particularly as Abderhalden discountenanced the use of such small quantities in his pregnancy test. We found, however, that the use of such small quantities of serum is perfectly admissible if the period of incubation is lengthened, as we have done, and if the quantity of water on the outside of the dialyzer is reduced to 10 c.c., of which 5 c.c. are then used in the final test with 0.1 c.c. of the ninhydrin solution. The very fact that with this technic results could be obtained which in the main go to support the claims of Fauser, is the best argument in favor of its admissibility.

We were led to the use of these small quantities of serum in our attempt to obviate the appearance of non-specific reactions with which every worker in this field is no doubt familiar, no matter whether he is willing to admit this in cold print or not. We have found it helpful, though by no means a certain guard against such reactions.

As regards the preparation of the tissues, I may say that every attempt was made to remove all traces of blood, and in many instances this was controlled by applying the phenolphthalin test for occult blood to the wash-water, and carrying the washing to the point of a negative reaction, even when the test was applied to the small amount of water that could be expressed from the tissues. The tissue, after being stripped of fat, connective tissue and macroscopically visible blood-vessels, was passed through a meat-hashing machine and then washed in running water for from twenty-four to forty-eight hours, after which it was coagulated by being placed in boiling water containing one drop of glacial acetic acid to the liter, as suggested by Abderhalden. The subsequent extraction with boiling water was then carried on in exact conformity with Abderhalden's method. As a matter of fact, the tissues to be used on a given day were boiled out at least half a dozen times on the day preceding, and then again as many times on the working-day, and to the point at which not the slightest reaction could be detected even on standing for half an hour in artificial light, which always accentuates the reactions. It will thus be noted that every precaution was taken to guard against sources of avoidable error, to which end the use of the small quantities of serum with the prolonged incubation certainly would tend to increase the number of negative instead of positive reactions.

The serums were always examined in sets of ten, without the slightest knowledge on our part of the clinical diagnosis, which was furnished only after our results had been announced.

With these precautions given I hardly think that our work is open to criticism from the standpoint of technic, so far at least as our present demands on the technic go, but neither am I ready to admit that a true sex-gland reaction may be obtained in the functional psychoses outside of dementia praecox. Before this question can be definitely answered, our technic must be radically improved. I feel very strongly that the underlying principle is correct, that we are dealing with a reaction which is in a certain sense specific even now with the imperfect technic at our command, but which is readily marred by apparently non-specific collateral or simultaneous reactions. Were this not true then one should obtain only definitely positive or definitely negative results; but as a matter of fact, in our experience at least, a correct "laboratory diagnosis" was frequently possible only when the ultimate results were compared with one another. If, for example, the dialysates were tested after an incubation of only twenty-four hours, using testicular tissue in combination with male serums, negative reactions only were observed, and our inference, had the examination ceased at this point, would have been that none of the serums had been taken from praecox patients. After an incubation of another twenty-four hours one or two specimens would show a reaction perhaps, but of so feeble a degree that one would hardly venture to attach any significance to the reaction. After twelve hours further not only the two specimens just noted would give a reaction, but perhaps six or seven out of the ten cases. The reaction, however, would then be of varying intensity, the most intense color being obtained with the two specimens which showed a faint reaction after forty-eight hours. A third one would perhaps be quite marked, though less so, while the remainder would give a faint color only. If at this stage we were to interpret the two intense reactions only as positive reactions, a comparison with the clinical condition of the patient would reveal that these had been the only praecox cases of the series. On waiting still longer we would at times find that the entire series was blue, and had our examination been made at this time only, we should have been led into the error of announcing that from a laboratory point of view all ten were praecox cases.

The readiness with which a whole series or a part of a series will become positive as incubation is continued, is variable and more marked with some tissues than with others. On the whole, the most satisfactory and unequivocal results were obtained with testicular tissue, cortex and occasionally with Basedow thyroid, while there was very apt to be an appalling blueness of the specimens when ovarian tissue was used, unless indeed the period of incubation was shortened by about twenty-four hours. Such variations Abderhalden would no doubt explain on the assumption that our tissues were not sufficiently free from blood, and this explanation seems to have been the accepted one in the case of many of the results that have been contrary to expectations, but although some of the abnormal findings may have been due to this cause, there must be still other factors which are operative in this direction.

This is strongly suggested by various incidental observations. Thus on one occasion we found that whereas practically all of twelve serums taken from divers mental cases gave positive reactions with ovarian tissue, but one of the same series reacted with blood-clot by itself. Had the latter parallel tests not been made the results with ovarian tissue would have been open to criticism on the supposititious basis that the tissues had not been washed free from blood, since errors due to faulty dialyzers or to imperfect extraction could be excluded. Such an assumption, however, is invalidated by the results which were obtained when the same serums were directly combined with blood clot. In this connection a number of observations which were made when animal tissue was substituted for human tissue acquire a certain significance as likewise suggesting the operation of extraneous factors.

Fuchs and Freund announced not long ago that they found beef testicle and beef ovary as efficacious as the corresponding human organs. We had already made the observation that rabbit testicle also may give apparently specific reactions, and in a series of ten cases could verify Fuchs and Freund's observations in reference to beef testicle, also, providing that the period of incubation was interrupted at a certain time. If this is exceeded, non-specific reactions appear, and, as in the case of the human organs, we found that these are more apt to occur early when ovarian tissue was used than in the case of testicular tissue. Such reactions can hardly be explained except on the assumption that aside from possible specific factors non-specific influences also are at work, and until these factors are known but little real headway in the application of this interesting field of investigation to clinical medicine will be possible. It would accordingly seem highly desirable if a number of the large army of workers in this field were to abandon the paths which have hitherto been pursued, and to devote their attention to a study of the fundamental physiologic principles which are involved. When once this basis has been furnished the day will not be far distant when "organ diagnosis" will become a possibility. It is my firm conviction that such a day is actually before us and hence that Abderhalden's basic work in this field should be viewed as one of the most important contributions to modern experimental medicine.

With our present knowledge it is of course impossible to draw any far-reaching conclusions concerning the significance of the sex-gland reaction in dementia praecox. Certain possibilities, however, suggest themselves which it may be well to discuss in brief.

When Abderhalden first discovered that during pregnancy a proteolytic ferment which is specifically directed against placental tissue, appears in the blood, he believed that this was the outcome of an invasion of the circulation by chorionic cells, which naturally would be alien to the blood. As a matter of fact it can easily be shown in the animal experiment that such ferments do appear when placental tissue is introduced into the organism by parenteral channels, and it is noteworthy that this will occur not only in female animals, but also in males. This, however, will also take place if instead of the tissue itself a corresponding extract (*Presssaft*) is used. So that we may conclude that the introduction of either cells or cell-products, so far as they are normally foreign to the blood, will divergent findings, however, in no way diminish the basic importance of Fauser's original observations from the standpoint either of diagnosis or of general biology and experimental medicine. The fact remains that in dementia praecox a positive reaction is the rule, and that in the purely functional psychoses it is the exception. Its possible occurrence in paresis and alcoholic insanity scarcely diminishes the importance of the reaction from this point of view.

How to explain our positive findings in manic-depressive cases I do not know. It is possible that some of these cases were really praecox cases, but it is not likely that this explanation would be applicable to all our exceptions to the general rule of Fauser that in manic-depressive insanity only negative reactions are obtained. We must, hence, either conclude that Fauser's rule does have exceptions, or that our positive findings were due to some error of technic. Before admitting or denying this possibility, it may not be out of place to enter in some detail on the general question of technic.

TECHNIC

As I have previously indicated, Fauser does not discuss the question of technic at all, but merely states that he followed the rules of Abderhalden implicitly and that his results, before Abderhalden "reenforced" those originally laid down, were practically the same as afterward. These rules have reference essentially to the condition of the serum, to that of the parchment thimbles, and of the tissues which are used as antigens.

Concerning the first factor, he asserts that the serum must be free from hemoglobin or corpuscles and uncontaminated by bacteria. These demands were complied with in every particular. The blood was collected in large vacuum tubes similar to the smaller Keidel tube, which permit of thorough dry sterilization, and can be handled with equal facility. The blood was placed in the ice-box over night, the serum separated by centrifugation the next morning and recentrifuged twice more before being used. No serum was used that was tinged reddish in the slightest degree. The dialyzers which were available at first were those originally advocated by Abderhalden, namely, No. 579 Schleicher and Schüll. As a large percentage of these were found to be too pervious, the firm placed a tighter thimble on the market, bearing the number 579a. The first lot of a hundred of these were found so tight, however, that using only 0.5 c.c. of serum in each, no reactions could be obtained with sex gland unless the incubation was extended to from sixty to sixty-six hours. Subsequently, a lot of supposedly tested thimbles were secured from Schoep of Halle, but these also were found to be rather tight, necessitating incubation for sixty hours with 0.5 c.c. of serum. Quite a number of these, moreover, had to be discarded, as they were permeable to serum, in spite of their having been sent out as "tested."

All the thimbles were, of course, tested with serum alone, and those discarded which allowed reacting substances to pass through. If the dialysate gave no reaction with ninhydrin, they received a single notch in the margin, and were then tested against serum in combination with a tissue which was known to react readily, such as a very cellular carcinoma, which gave reactions with practically every serum whether derived from a normal person or a patient; while when placed in the dialyzer by itself, the dialysate gave no reaction whatever with ninhydrin. Or, the thimbles were tested with an "unimportant" organ in a series of experiments, and those selected which gave reactions in the dialysate. Either procedure gives the same results as when tested with peptone alone. After having been shown to be permeable for substances resulting from the interaction of serum and tissue, the thimbles received two additional notches and were then set aside in jars under toluene until needed for an actual experiment. Early in our work we sterilized our dialyzing jars with the dialyzer and the necessary amount of water, in the steam sterilizer, before using them, but abandoned this when it was found that the permeability of the thimbles was thereby lessened.

After being used the thimbles were carefully washed under the tap, placed in jars under running water for several hours and then stored under water and toluene until needed. The average life of a thimble under such conditions, being in use for from three to four days of every week, certainly extends over several months.

I have pointed out above that in most of our experiments we used but 0.5 c.c. of serum to each thimble. We may be criticized on this point, particularly as Abderhalden discountenanced the use of such small quantities in his pregnancy test. We found, however, that the use of such small quantities of serum is perfectly admissible if the period of incubation is lengthened, as we have done, and if the quantity of water on the outside of the dialyzer is reduced to 10 c.c., of which 5 c.c. are then used in the final test with 0.1 c.c. of the ninhydrin solution. The very fact that with this technic results could be obtained which in the main go to support the claims of Fauser, is the best argument in favor of its admissibility.

We were led to the use of these small quantities of serum in our attempt to obviate the appearance of non-specific reactions with which every worker in this field is no doubt familiar, no matter whether he is willing to admit this in cold print or not. We have found it helpful, though by no means a certain guard against such reactions.

As regards the preparation of the tissues, I may say that every attempt was made to remove all traces of blood, and in many instances this was controlled by applying the phenolphthalin test for occult blood to the wash-water, and carrying the washing to the point of a negative reaction, even when the test was applied to the small amount of water that could be expressed from the tissues. The tissue, after being stripped of fat, connective tissue and macroscopically visible blood-vessels, was passed through a meat-hashing machine and then washed in running water for from twenty-four to forty-eight hours, after which it was coagulated by being placed in boiling water containing one drop of glacial acetic acid to the liter, as suggested by Abderhalden. The subsequent extraction with boiling water was then carried on in exact conformity with Abderhalden's method. As a matter of fact, the tissues to be used on a given day were boiled out at least half a dozen times on the day preceding, and then again as many times on the working-day, and to the point at which not the slightest reaction could be detected even on standing for half an hour in artificial light, which always accentuates the reactions. It will thus be noted that every precaution was taken to guard against sources of avoidable error, to which end the use of the small quantities of serum with the prolonged incubation certainly would tend to increase the number of negative instead of positive reactions.

The serums were always examined in sets of ten, without the slightest knowledge on our part of the clinical diagnosis, which was furnished only after our results had been announced.

With these precautions given I hardly think that our work is open to criticism from the standpoint of technic, so far at least as our present demands on the technic go, but neither am I ready to admit that a true sex-gland reaction may be obtained in the functional psychoses outside of dementia praecox. Before this question can be definitely answered, our technic must be radically improved. I feel very strongly that the underlying principle is correct, that we are dealing with a reaction which is in a certain sense specific even now with the imperfect technic at our command, but which is readily marred by apparently non-specific collateral or simultaneous reactions. Were this not true then one should obtain only definitely positive or definitely negative results; but as a matter of fact, in our experience at least, a correct "laboratory diagnosis" was frequently possible only when the ultimate results were compared with one another. If, for example, the dialysates were tested after an incubation of only twenty-four hours, using testicular tissue in combination with male serums, negative reactions only were observed, and our inference, had the examination ceased at this point, would have been that none of the serums had been taken from praecox patients. After an incubation of another twenty-four hours one or two specimens would show a reaction perhaps, but of so feeble a degree that one would hardly venture to attach any significance to the reaction. After twelve hours further not only the two specimens just noted would give a reaction, but perhaps six or seven out of the ten cases. The reaction, however, would then be of varying intensity, the most intense color being obtained with the two specimens which showed a faint reaction after forty-eight hours. A third one would perhaps be quite marked, though less so, while the remainder would give a faint color only. If at this stage we were to interpret the two intense reactions only as positive reactions, a comparison with the clinical condition of the patient would reveal that these had been the only praecox cases of the series. On waiting still longer we would at times find that the entire series was blue, and had our examination been made at this time only, we should have been led into the error of announcing that from a laboratory point of view all ten were praecox cases.

The readiness with which a whole series or a part of a series will become positive as incubation is continued, is variable and more marked with some tissues than with others. On the whole, the most satisfactory and unequivocal results were obtained with testicular tissue, cortex and occasionally with Basedow thyroid, while there was very apt to be an appalling blueness of the specimens when ovarian tissue was used, unless indeed the period of incubation was shortened by about twenty-four hours. Such variations Abderhalden would no doubt explain on the assumption that our tissues were not sufficiently free from blood, and this explanation seems to have been the accepted one in the case of many of the results that have been contrary to expectations, but although some of the abnormal findings may have been due to this cause, there must be still other factors which are operative in this direction.

This is strongly suggested by various incidental observations. Thus on one occasion we found that whereas practically all of twelve serums taken from divers mental cases gave positive reactions with ovarian tissue, but one of the same series reacted with blood-clot by itself. Had the latter parallel tests not been made the results with ovarian tissue would have been open to criticism on the supposititious basis that the tissues had not been washed free from blood, since errors due to faulty dialyzers or to imperfect extraction could be excluded. Such an assumption, however, is invalidated by the results which were obtained when the same serums were directly combined with blood clot. In this connection a number of observations which were made when animal tissue was substituted for human tissue acquire a certain significance as likewise suggesting the operation of extraneous factors.

Fuchs and Freund announced not long ago that they found beef testicle and beef ovary as efficacious as the corresponding human organs. We had already made the observation that rabbit testicle also may give apparently specific reactions, and in a series of ten cases could verify Fuchs and Freund's observations in reference to beef testicle, also, providing that the period of incubation was interrupted at a certain time. If this is exceeded, non-specific reactions appear, and, as in the case of the human organs, we found that these are more apt to occur early when ovarian tissue was used than in the case of testicular tissue. Such reactions can hardly be explained except on the assumption that aside from possible specific factors non-specific influences also are at work, and until these factors are known but little real headway in the application of this interesting field of investigation to clinical medicine will be possible. It would accordingly seem highly desirable if a number of the large army of workers in this field were to abandon the paths which have hitherto been pursued, and to devote their attention to a study of the fundamental physiologic principles which are involved. When once this basis has been furnished the day will not be far distant when "organ diagnosis" will become a possibility. It is my firm conviction that such a day is actually before us and hence that Abderhalden's basic work in this field should be viewed as one of the most important contributions to modern experimental medicine.

With our present knowledge it is of course impossible to draw any far-reaching conclusions concerning the significance of the sex-gland reaction in dementia praecox. Certain possibilities, however, suggest themselves which it may be well to discuss in brief.

When Abderhalden first discovered that during pregnancy a proteolytic ferment which is specifically directed against placental tissue, appears in the blood, he believed that this was the outcome of an invasion of the circulation by chorionic cells, which naturally would be alien to the blood. As a matter of fact it can easily be shown in the animal experiment that such ferments do appear when placental tissue is introduced into the organism by parenteral channels, and it is noteworthy that this will occur not only in female animals, but also in males. This, however, will also take place if instead of the tissue itself a corresponding extract (*Presssaft*) is used. So that we may conclude that the introduction of either cells or cell-products, so far as they are normally foreign to the blood, will cause the appearance of corresponding ferments. As chorionic cells and hence [illegible] however, are not found in the normal organism except at certain periods which may be separated from one another by long intervals, whereas the sex glands and their cells are after all constant constituents of the animal body, it would seem *a priori* unlikely that in dementia praecox the appearance of the corresponding ferments should be referable to the action of either *normal* cells or *normal* cell constituents.

In this connection certain observations of Lampé and his co-workers are of interest. These investigators found that in Basedow's disease a more constant and more intense reaction is obtained with Basedow thyroid than with normal thyroid, and they accordingly conclude that in the disease in question we are not dealing with a hyperfunction, but with a perverted function of the gland. Otherwise it would be difficult to understand why the animal body should react with the appearance of a specific ferment to a mere increase of a normal secretion. We should indeed be forced to the conclusion that the reaction must be in response to the appearance in the circulation of the cells themselves; but we should also have to conclude that the chemical structure of these cells must be different from the normal, as otherwise the serum of patients with Basedow's disease should react just as well with normal thyroid as with Basedow thyroid. This possibility of course exists. But we might then ask ourselves if an abnormally constructed cell would not also be likely to furnish an abnormal secretion, in which case the reaction might after all be referable to certain constituents of this altered secretion rather than to the appearance in the circulation of the cells themselves. However this may be, it is evident that either an abnormally constructed cell or abnormally constituted cell-products may theoretically produce the same result.

In considering this question in connection with dementia praecox the thought of course suggests itself that here also we may be dealing with a perverted function of those cells which are concerned in the production of the internal secretion of the sex glands. Evidently, it would be advisable to study, on the one hand, the intensity of the ferment reaction against normal sex gland, and on the other, the reaction against sex gland derived from praecox cases. This has not as yet been done, but would seem to be the most important next step. Practically all the reactions which we obtained with testicular tissue were relatively slight, and it would accordingly go far toward establishing the existence of a perverted function of the cells furnishing an internal secretion, if it could be established that more marked reactions were obtainable with praecox than with normal organs.

That the interstitial cells of the testicles are concerned in the reaction we could demonstrate by combining the patient's serum, on the one hand with infantile tissue, and on the other with adult testicle, when reactions of equal intensity were obtained with the two antigens.

Supposing that the stimulus for the production of the ferments in question were to emanate from the sex glands, the next problem would be to ascertain the origin of the ferments. During his early studies of the pregnancy reaction Abderhalden believed that the ferment originated from the blood-cells, having the leukocytes more particularly in mind. Subsequently, however, he seems to have abandoned this view, and in a late publication he expresses the belief that the ferments might possibly be formed in the very organs against which their activity is directed. One reason which led to this change of view was the observation that whereas antitesticular ferments appear in the blood-serum of normal rabbits following the parenteral introduction of testicular cells, this does not occur in castrated animals. On the other hand, however, it must be remembered that the formation of antichorionic ferments may be evoked artificially both in male and female animals, so that we may conclude that whereas certain ferments may originate in the homologous organs, others may be produced by heterologous cells. This would be in perfect accord with what is known to occur in the production of tetanus antitoxin as a consequence of the introduction of the corresponding toxin.

Even though immunization with normal sex-gland tissue should evoke the liberation of corresponding ferments in the normal organ, it would not follow that other tissues might not become similarly active if an abnormal secretion were to enter the circulation.

Every cell of course contains proteolytic ferments which are capable of causing the digestion of homologous cells, when certain inhibitory factors fall away (for example, autolysis after death), and it would seem the simplest to assume that these ferments are given off by the cell when corresponding cells or cell-products are introduced into the circulation. But it remains to be seen whether the ferments then occurring in the blood are identical with the normal ferments of the normal cells and those occurring in the blood under manifestly pathologic conditions.

Considering the problem from the clinical side, the all-important question of course suggests itself whether or not the reaction has any relation to the pathogenesis of dementia praecox. Theoretically, this is of course perfectly possible. Granted that antisex-gland ferments do occur in the circulation in dementia praecox, and that their presence were the outcome of the appearance in the circulation of an abnormal secretion or of abnormal cells, then we may also assume that digestion of these cells or cell-products will take place, and that all conditions would thus be given for a chronic protein intoxication which might very well expend itself on the central nervous system. Should this be true, then we might also expect that the administration of sex gland to such patients would cause an aggravation of the patient's condition, while partial or entire castration, possibly combined with the transplantation of normal organs might similarly be expected to have a beneficial influence. Evidently, the problem is now open to investigation from many sides, and it does not seem unreasonable to expect that definite advances will be achieved in the near future.

In conclusion, I wish to express my appreciation of the courtesy and cooperation of the staff of the Sheppard and Enoch Pratt Hospital, which made the work outlined above possible.

Public Hygiene Depends on the Individual.—Power to regulate water-supply and sewage-disposal or to vacate or destroy property unfit for habitation helps materially in improving the sanitation of the home, but it fails to reach that class of people whose personal habits render any home unfit for occupancy.—J. H. Landis, in *Am. Jour. Pub. Health.*

RESULTS OF RADIUM IN CANCER

H. H. JANEWAY, M.D.
Attending Surgeon to General Memorial Hospital
NEW YORK

The application of radium to the treatment of cancer cannot be considered new. It was first tried nine years ago; and since that time Wickham has been constantly engaged in its application to disease, and especially to cancer, in the very city which may be termed the home of radium.

The Laboratoire biologique du radium was organized in the early part of 1906. The object of this institute was to serve as a center for radium therapy. It possessed a chemical, a physiologic and a physical department, the last furnished with the most sensitive instruments of the Curies' laboratory. These departments, respectively, were under the charge of a competently trained chemist, physiologist and physicist. The therapeutic portion of the work was under the direction of Dr. Wickham. Since 1906, one thousand patients, afflicted with various forms of cancer, have been treated. The results of this treatment have been published in two books, one of which appeared in 1910 and the other in 1913. In the second publication, Dr. Wickham furnishes the following summary of his opinion regarding the action of radium on cancer:

1. Radium causes an undeniably destructive modification of the malignant cells.
2. Malignant tissues display a special and very selective susceptibility to the influence of radium.
3. This destructive action extends to a depth varying up to 9 cm., according to the dosage used and the sensitiveness of the neoplasm.
4. This action, even to the depth mentioned, occurs with the maintenance of the relative integrity of the normal tissues traversed.
5. The action, nevertheless, is not complete enough to warrant the use of radium as a primary therapeutic agent in any form of operable cancer, with the single exception of cancer of the skin.

Cancer of the skin, because of its superficial character and relative benignity, will always constitute a form of cancer belonging to an entirely different category from all other varieties. It forms the first of the groups into which Wickham divides the disease for the consideration of radium therapy. Regarding this group, he says:

> As far as our experience goes, in judging from our statistics, which contain several hundred cases of different varieties, we have arrived at the conclusion that in a majority of epitheliomata of the skin, even in the gravest cases, radium is undoubtedly superior to any other therapeutic agent, both on account of its direct curative action and because of the simplicity of its application.

In some particularly grave cases radium has been most effective in his hands. Even advanced, entirely inoperable forms, characterized by deep extension and in some instances by the presence of large tumors, have scarcely altered his statistics for the worse. In compiling these statistics, the element of time has been carefully considered.

Though it is only in this first group that radium deserves an important place in the fight against cancer, it is nevertheless by no means devoid of usefulness in other forms of the disease. An acquaintance with what has been accomplished in these other varieties is therefore important, for even though the results of radium treatment do not demonstrate its curability in the more advanced cancers, yet they furnish information concerning the extent to which it is able to produce the same selective destructive action on cancer tissue in general.

These other types of cancer, in which are grouped all the more serious and more important varieties, may be considered, from the point of view of radium therapy, under the two main divisions of operable and inoperable cancer.

Considering first the operable group (those cases capable of complete extirpation), Wickham makes the following significant statement:

> Operable cancer should be operated on immediately without delay. This is an absolutely fixed rule.

The inoperable forms are discussed under the different subdivisions of the histologic varieties of cancer and of cancer in the various locations within the body. In nearly all of the inoperable forms it is permissible to use radium, because of the relief from many of the objective and subjective symptoms which it not infrequently affords.

Wickham states that the various sorts of sarcoma yield to radiation more quickly than any of the many types of epithelial cancer. Lymphadenoma and mycosis fungoides are more susceptible than even sarcoma. He is able to report very important palliative results in the treatment of cancer from all regions of the body, and has witnessed an entire retrogression of many large inoperable epitheliomas of the skin and of some breast tumors. Types of the cases similar to those of Wickham have been described also by Dominici (who shares largely in the credit for the work of the institution), together with many photographs, in a monograph entitled, "The Technique and Results of Radium Therapy in Malignant Diseases."

Isolated instances do exist of apparent cures in some of the inoperable forms of cancer of the second group, and there is a fairly large proportion of cases in which the retrogression at the primary site of the tumor has prolonged the life of the patient and rendered him more comfortable. In no instance, however, has there been a complete eradication of the ultimate ramifications of the disease.

The only conclusion to be drawn from these results is that while the influence of radium on all types of cancer is a favorable one, it does not extend to the limits of the disease in any but the most superficial varieties.

The work of the Radium Institute of London, while much more recent, is second to none in importance. The institute possesses 4 gm. of radium — an amount far exceeding the quantity owned by any other single institution.

In the institute's report[1] of 467 cases of cancer treated during 1912, no patient has been classified as cured, inasmuch as it is not permissible to consider cancer in this light until there has been a freedom from recurrence for a period of at least three years. The most favorable results are reported as only apparent cures, though certain of them may later prove to be actual ones.

Of 101 patients with the slow-growing, benign forms of cancer of the skin, 31 were apparently cured,

---

[1] Pinch, A. E. Hayward: Brit. Med. Jour., 1913.

41 improved, and 12 did not improve. In cancer of *the rest of the body, including practically all varieties,* there were only 15 cases apparently cured, 156 improved, and 45 did not improve. Of the 15 cases apparently cured, 4 were skin cancers occurring on the hand and cheek, 3 were cancers of the uterus, 2 were breast-cancers, 1 was a cancer of the thyroid gland, 1 was a cancer of the rectum, 1 was a tumor of the parotid gland, and 2 were sarcomas. Among all these cases the cancers of the uterus, breast and rectum are most significant. Cases 180, 5109 and 5199 have been selected as the cancers of the uterus which were apparently cured. In all three of these patients the cancer had returned after operation. Following radium treatment, there was, in each instance, an entire disappearance of the tumor mass and of all induration. It is supposed that Case 35 was the case of cured cancer of the rectum. It was an inoperable cancer, and after an interval of eight months from the time of its treatment with radium, no sign of the growth could be detected. The improvement in Cases 48 and 186 was so great that only the most conservative judgment could exclude them from the category of the apparently cured. Of the tumors of the breast, one was a case of Paget's disease, and therefore superficial. Case 5100 has been selected as the apparently cured case of cancer of the breast, in which the patient concerned had a recurrent cancer. At the beginning of the treatment she had six nodules the size of a walnut which had recurred in the scar. It is interesting to note that the recurrence in this patient had been unsuccessfully treated with the Roentgen ray before the application of radium.

The foregoing results fully confirm the conclusions of Wickham. With the lapse of time they may prove to be even more significant. At present they in no way *alter his deductions and lend no support to the view* that radium can be considered a cure for cancer. They convincingly demonstrate that its specific effect on the disease is not limited to any one of its forms.

In Vienna an important work with radium has been established. In June, 1912, the Vienna Radium Institute began its researches with half a gram of radium, an additional gram being furnished in June, 1913. The total amount, 1.5 gm., is very large, and quite sufficient to test the efficacy of radium on cancer. The institute has been founded as a central station for the distribution of radio-activity to the various departments of the Vienna Hospital. Riehl[2] has reported the results obtained by the use of radium on superficial cutaneous cancer, Wertheim,[3] on its application to cancer of the uterus and Ranzi, Schüller and Sparmann,[4] the results of the treatment of cancer of the various organs. Riehl has treated 114 patients afflicted with skin cancer, and his observations regarding its favorable influence on this form of the disease agree with the conclusions of others. He considers that in this form of cancer the application of radium, even in small quantities, is preferable to other methods of treatment. One of his patients may be referred to as an illustration: A tumor the size of a child's head had retrogressed, except for the deeper extension of the growth, which ultimately had reached the esophagus and caused the death of the patient. Wertheim states that he has treated nine cases of inoperable cancer of the uterus, in a number of which the previously fixed *tumor again became movable;* there was also a considerable reduction in the size of the growth, and altogether the patients improved to such an extent that it was possible to consider radical removal. Notwithstanding all this, it is impossible for him to view even such improvement as at all approaching a cure.

Ranzi, Schüller and Sparmann have treated 53 patients: 6 after operation, for the purpose of preventing recurrence, and 47 with inoperable tumors existing at the time that treatment with radium was instituted. Three of the 6 patients treated palliatively showed an extensive recurrence after a short time. The other 3 gave no evidence of recurrence after a period of three months in 2 of the patients, and two months in the case of the third.

The accompanying table shows the locations and varieties of all the cancers treated.

LOCATIONS AND VARIETIES OF CANCERS TREATED BY RANZI, SCHUELLER AND SPARMANN

	Patients
Sarcoma of the cranium	4
Cancer of the upper jaw	3
Cancer of the neck	6
Cancer of the breast	4
Cancer of the skin	4
Cancer of the penis	1
Melanosarcoma of the skin	1
Cancer of the esophagus	5
Cancer of the stomach	2
Cancer of the rectum	3
Cancer of the interior of the mouth	8
Cancer of the tongue	9
Cancer of the thyroid gland	1
Cancer of the pleura	1
Cancer of the nasopharyngeal cavity	1
	53

Notwithstanding the fact that a series of these cases received a high dosage of radio-activity, in only three instances of the whole fifty-three was there a continuous retrogression of the tumor. One of these three patients had a recurrent cancer of the tongue, about ½ to ¾ inch in diameter; another had a superficial epithelioma of the nose of the benign type, and in this case, while the growth on the nose was healing, a secondary extension of the disease on the upper jaw increased in size; the third patient in this group was a woman with a carcinoma of the tongue, which completely disappeared.

After deducting from the 53 patients 19 who either discontinued treatment or were lost sight of, there remained 34 from whom it was possible to draw conclusions. Of these, 6 died during the course of the treatment; 11 were essentially improved; 6 were very slightly improved, and 3 were made worse. Wertheim concludes with the statement that radium can be considered only a contributory agent in dealing with cancer. It produces solely a limited effect, and therefore its use in operable cancer is equivalent to the denial of principles in dealing with the malignant disease which are already too well founded to permit of question.

The Samaritan Hospital in Heidelberg has also made a report on the action of radium on cancer. This report deserves mention because of the foundation in this hospital of a work devoted exclusively to the cure of cancer, but the value of the work is much less than that of the three institutes already referred to because of the fact that only 20 mg. of radium were available. The report was published by Caan,[5] the details of 130 cases being given, of which 105 had carcinoma and 11 sarcoma. Fifty per cent. of all the cases treated showed the effects of a favorable influence attributable to cancer. Of 38 cancers of the breast a definite improvement was observed in 27 instances. In 8 of the 27 patients a complete retrogression of superficial tumors was noted (in one instance the size of a hen's egg); in 3 of this group of 27 patients the objective improvement was so marked that a previously inoperable growth became shrunken and movable to the extent of permitting consideration of a radical operation. In 5 out of 7 skin cases, healthy granulations replaced the tumor tissue. In 8 patients with malignant lymphomas, there was a complete disappearance of the tumor.

[4] Ranzi, E.; Schüller, H., and Sparmann, R.: Wien. klin. Wchnschr., 1913, xxvi, 1651.

Caan further states, in summing up, that radium must be considered an important agent in the fight against malignant disease. In about 50 per cent. of his 130 cases he had produced improvement which may be described as a softening and retrogression of the tumor and an amelioration in the subjective symptoms of the patient. In two more recent publications,[6] Czerny and Caan publish their later experiences with the radio-active treatment of cancer. These publications concern more especially the use of mesothorium and thorium X — two very strong radio-active preparations considered by Caan quite as powerful as radium. It is therefore proper to consider them here. They furnished little additional information, however. Improvement was produced in about 40 or 50 per cent. of the cases, but no patient was cured. Caan concludes by stating that in cases of cancer susceptible to radical removal, treatment by mesothorium and thorium X should in no instance supersede the knife.

It is evident from a comparison of these various reports that the subject has been approached from different attitudes in France, England and Germany. It is quite easy to read between the lines of Wickham's book a great deal of enthusiasm for the treatment of cancer by radium; it is equally obvious that the Germans have expressed themselves most conservatively. The report of the English institute, on the other hand, draws no conclusions whatsoever, but simply consists of a statement of facts. Nevertheless, a comparison of these reports presented from these different attitudes, discloses a remarkable agreement which it would be easy to confirm by reference to numerous isolated publications on the use of radium from independent workers. Each report justifies the statement that radium produces a selective destructive action on the majority of cancers, but that this action never reaches to the more distant extensions of its deeper and more serious forms. Indeed, there is good ground for belief that unless the greatest care is used in the application of radium, the more distant portions of the tumor will be stimulated to more active growth. All observers of the action of radium on cancer have expressed the belief that an insufficient dosage of radio-activity may stimulate tumor growth. A moment's reflection will make clear how rapidly the total amount of radiation must diminish at points increasingly distant from the center of radiation. Aside from the amount of radiation absorbed, the number of rays diminish inversely as the square of the distance. All users of radium are most emphatic in expressing the belief that no operable cancers, except those of the skin, should be treated by radium in preference to operation.

It is therefore permissible to consider that the true position of radium in the treatment of cancer, with the present methods of application, is a settled matter. While it will destroy cancer tissue in a dosage not affecting normal tissues, it does not cure the disease unless it is quite superficial or of a variety peculiarly susceptible to its influence. The establishment of the fact that we have in radio-activity an agent which will at all specifically affect cancer, is of very great importance — all the more so, inasmuch as no other agent has thus far been discovered which in any degree approaches its effectiveness. A knowledge of these facts offers every encouragement to the belief that a more successful method of applying this remedy may yet be discovered; the lines of experimentation are clearly indicated; the whole question merely reduces itself to the even distribution of the proper dosage throughout all involved tissues. The realization of this end is all in the future and purely speculative. At present, radium may only supplement, but not replace, the knife.

THE AUTOSEROSALVARSAN TREATMENT OF SYPHILIS OF THE CENTRAL NERVOUS SYSTEM

SECOND PAPER

G. W. McCASKEY, A.M., M.D.
Professor of Medicine, Indiana University School of Medicine
FORT WAYNE, IND.

Since the publication of my paper on "The Autoserosalvarsan Treatment of Syphilis of the Central Nervous System,"[1] thirteen additional cases have been treated. It is not the purpose of this communication to report these cases. During the clinical study of these twenty cases, however, many practical questions have arisen, a brief discussion of which appears to be timely. The points which I propose to discuss are along the lines of safety, efficiency and convenience. They are three in number:

1. The problem of asepsis.
2. Time of withdrawal of blood for serum.
3. Dosage and dilution of salvarsanized serum.

I. THE PROBLEM OF ASEPSIS

In an early one of my last series of eleven cases an accidental infection of the spinal canal occurred. This patient has completely recovered from the infection, but the possibility of the recurrence of such an accident demanded such a critical review and revision of methods as would make it impossible. The opportunities and dangers of contamination in the preparation of a serum for intraspinal injection by an "open-air method" are manifest. Instruments, receptacles and appliances were above suspicion by reason of the effectiveness of modern hospital methods of sterilization. The skin of the patient at points of puncture,

41 improved, and 12 did not improve. In cancer of the rest of the body, including practically all varieties, there were only 15 cases apparently cured, 156 improved, and 45 did not improve. Of the 15 cases apparently cured, 4 were skin cancers occurring on the hand and cheek, 3 were cancers of the uterus, 2 were breast-cancers, 1 was a cancer of the thyroid gland, 1 was a cancer of the rectum, 1 was a tumor of the parotid gland, and 2 were sarcomas. Among all these cases the cancers of the uterus, breast and rectum are most significant. Cases 180, 5109 and 5199 have been selected as the cancers of the uterus which were apparently cured. In all three of these patients the cancer had returned after operation. Following radium treatment, there was, in each instance, an entire disappearance of the tumor mass and of all induration. It is supposed that Case 35 was the case of cured cancer of the rectum. It was an inoperable cancer, and after an interval of eight months from the time of its treatment with radium, no sign of the growth could be detected. The improvement in Cases 48 and 186 was so great that only the most conservative judgment could exclude them from the category of the apparently cured. Of the tumors of the breast, one was a case of Paget's disease, and therefore superficial. Case 5100 has been selected as the apparently cured case of cancer of the breast, in which the patient concerned had a recurrent cancer. At the beginning of the treatment she had six nodules the size of a walnut which had recurred in the scar. It is interesting to note that the recurrence in this patient had been unsuccessfully treated with the Roentgen ray before the application of radium.

The foregoing results fully confirm the conclusions of Wickham. With the lapse of time they may prove to be even more significant. At present they in no way alter his deductions and lend no support to the view that radium can be considered a cure for cancer. They convincingly demonstrate that its specific effect on the disease is not limited to any one of its forms.

In Vienna an important work with radium has been established. In June, 1912, the Vienna Radium Institute began its researches with half a gram of radium, an additional gram being furnished in June, 1913. The total amount, 1.5 gm., is very large, and quite sufficient to test the efficacy of radium on cancer. The institute has been founded as a central station for the distribution of radio-activity to the various departments of the Vienna Hospital. Riehl[2] has reported the results obtained by the use of radium on superficial cutaneous cancer, Wertheim,[3] on its application to cancer of the uterus and Ranzi, Schüller and Sparmann,[4] the results of the treatment of cancer of the various organs. Riehl has treated 114 patients afflicted with skin cancer, and his observations regarding its favorable influence on this form of the disease agree with the conclusions of others. He considers that in this form of cancer the application of radium, even in small quantities, is preferable to other methods of treatment. One of his patients may be referred to as an illustration: A tumor the size of a child's head had retrogressed, except for the deeper extension of the growth, which ultimately had reached the esophagus and caused the death of the patient. Wertheim states that he has treated nine cases of inoperable cancer of the uterus, in a number of which the previously fixed tumor again became movable; there was also a considerable reduction in the size of the growth, and altogether the patients improved to such an extent that it was possible to consider radical removal. Notwithstanding all this, it is impossible for him to view even such improvement as at all approaching a cure.

Ranzi, Schüller and Sparmann have treated 53 patients: 6 after operation, for the purpose of preventing recurrence, and 47 with inoperable tumors existing at the time that treatment with radium was instituted. Three of the 6 patients treated palliatively showed an extensive recurrence after a short time. The other 3 gave no evidence of recurrence after a period of three months in 2 of the patients, and two months in the case of the third.

The accompanying table shows the locations and varieties of all the cancers treated.

LOCATIONS AND VARIETIES OF CANCERS TREATED BY RANZI, SCHUELLER AND SPARMANN

	Patients
Sarcoma of the cranium	4
Cancer of the upper jaw	3
Cancer of the neck	6
Cancer of the breast	4
Cancer of the skin	4
Cancer of the penis	1
Melanosarcoma of the skin	1
Cancer of the esophagus	5
Cancer of the stomach	2
Cancer of the rectum	3
Cancer of the interior of the mouth	8
Cancer of the tongue	9
Cancer of the thyroid gland	1
Cancer of the pleura	1
Cancer of the nasopharyngeal cavity	1
	53

Notwithstanding the fact that a series of these cases received a high dosage of radio-activity, in only three instances of the whole fifty-three was there a continuous retrogression of the tumor. One of these three patients had a recurrent cancer of the tongue, about ½ to ¾ inch in diameter; another had a superficial epithelioma of the nose of the benign type, and in this case, while the growth on the nose was healing, a secondary extension of the disease on the upper jaw increased in size; the third patient in this group was a woman with a carcinoma of the tongue, which completely disappeared.

After deducting from the 53 patients 19 who either discontinued treatment or were lost sight of, there remained 34 from whom it was possible to draw conclusions. Of these, 6 died during the course of the treatment; 11 were essentially improved; 6 were very slightly improved, and 3 were made worse. Wertheim concludes with the statement that radium can be considered only a contributory agent in dealing with cancer. It produces solely a limited effect, and therefore its use in operable cancer is equivalent to the denial of principles in dealing with the malignant disease which are already too well founded to permit of question.

The Samaritan Hospital in Heidelberg has also made a report on the action of radium on cancer. This report deserves mention because of the foundation in this hospital of a work devoted exclusively to the cure of cancer, but the value of the work is much less than that of the three institutes already referred to because of the fact that only 20 mg. of radium were available. The report was published by Caan,[5] the details of 130 cases being given, of which 105 had carcinoma and 11 sarcoma. Fifty per cent. of all the cases treated showed the effects of a favorable influence attributable to cancer. Of 38 cancers of the breast a definite improvement was observed in 27 instances. In 8 of the 27 patients a complete retrogression of superficial tumors was noted (in one instance the size of a hen's egg); in 3 of this group of 27 patients the objective improvement was so marked that a previously inoperable growth became shrunken and movable to the extent of permitting consideration of a radical operation. In 5 out of 7 skin cases, healthy granulations replaced the tumor tissue. In 8 patients with malignant lymphomas, there was a complete disappearance of the tumor.

[3] Wertheim: Wien. klin. Wchnschr., 1913, xxvi, 1648.
[4] Ranzi, E.; Schüller, H., and Sparmann, R.: Wien. klin. Wchnschr., 1913, xxvi, 1651.

Caan further states, in summing up, that radium must be considered an important agent in the fight against malignant disease. In about 50 per cent. of his 130 cases he had produced improvement which may be described as a softening and retrogression of the tumor and an amelioration in the subjective symptoms of the patient. In two more recent publications,[6] Czerny and Caan publish their later experiences with the radio-active treatment of cancer. These publications concern more especially the use of mesothorium and thorium X — two very strong radio-active preparations considered by Caan quite as powerful as radium. It is therefore proper to consider them here. They furnished little additional information, however. Improvement was produced in about 40 or 50 per cent. of the cases, but no patient was cured. Caan concludes by stating that in cases of cancer susceptible to radical removal, treatment by mesothorium and thorium X should in no instance supersede the knife.

It is evident from a comparison of these various reports that the subject has been approached from different attitudes in France, England and Germany. It is quite easy to read between the lines of Wickham's book a great deal of enthusiasm for the treatment of cancer by radium; it is equally obvious that the Germans have expressed themselves most conservatively. The report of the English institute, on the other hand, draws no conclusions whatsoever, but simply consists of a statement of facts. Nevertheless, a comparison of these reports presented from these different attitudes, discloses a remarkable agreement which it would be easy to confirm by reference to numerous isolated publications on the use of radium from independent workers. Each report justifies the statement that radium produces a selective destructive action on the majority of cancers, but that this action never reaches to the more distant extensions of its deeper and more serious forms. Indeed, there is good ground for belief that unless the greatest care is used in the application of radium, the more distant portions of the tumor will be stimulated to more active growth. All observers of the action of radium on cancer have expressed the belief that an insufficient dosage of radio-activity may stimulate tumor growth. A moment's reflection will make clear how rapidly the total amount of radiation must diminish at points increasingly distant from the center of radiation. Aside from the amount of radiation absorbed, the number of rays diminish inversely as the square of the distance. All users of radium are most emphatic in expressing the belief that no operable cancers, except those of the skin, should be treated by radium in preference to operation.

It is therefore permissible to consider that the true position of radium in the treatment of cancer, with the present methods of application, is a settled matter. While it will destroy cancer tissue in a dosage not affecting normal tissues, it does not cure the disease unless it is quite superficial or of a variety peculiarly susceptible to its influence. The establishment of the fact that we have in radio-activity an agent which will at all specifically affect cancer, is of very great importance — all the more so, inasmuch as no other agent has thus far been discovered which in any degree approaches its effectiveness. A knowledge of these facts offers every encouragement to the belief that a more successful method of applying this remedy may yet be discovered; the lines of experimentation are clearly indicated; the whole question merely reduces itself to the even distribution of the proper dosage throughout all involved tissues. The realization of this end is all in the future and purely speculative. At present, radium may only supplement, but not replace, the knife.

THE AUTOSEROSALVARSAN TREATMENT OF SYPHILIS OF THE CENTRAL NERVOUS SYSTEM

SECOND PAPER

G. W. McCASKEY, A.M., M.D.
Professor of Medicine, Indiana University School of Medicine
FORT WAYNE, IND.

Since the publication of my paper on "The Autoserosalvarsan Treatment of Syphilis of the Central Nervous System,"[1] thirteen additional cases have been treated. It is not the purpose of this communication to report these cases. During the clinical study of these twenty cases, however, many practical questions have arisen, a brief discussion of which appears to be timely. The points which I propose to discuss are along the lines of safety, efficiency and convenience. They are three in number:

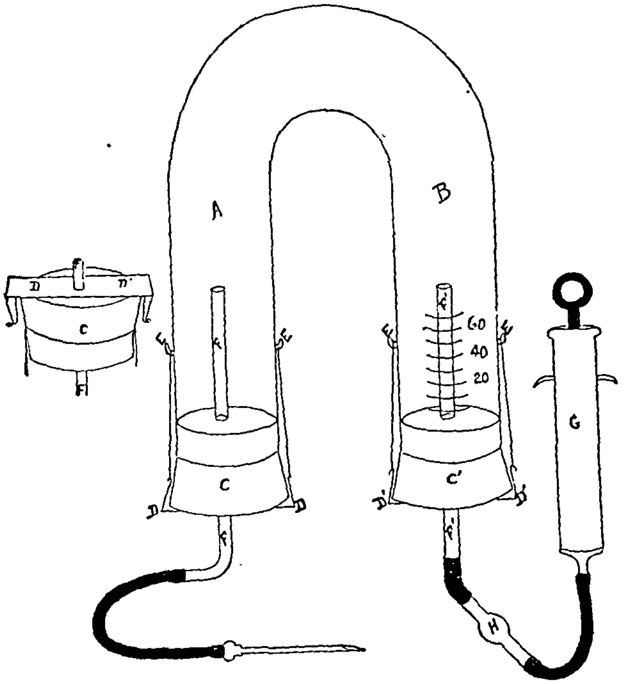
1. The problem of asepsis.
2. Time of withdrawal of blood for serum.
3. Dosage and dilution of salvarsanized serum.

I. THE PROBLEM OF ASEPSIS

In an early one of my last series of eleven cases an accidental infection of the spinal canal occurred. This patient has completely recovered from the infection, but the possibility of the recurrence of such an accident demanded such a critical review and revision of methods as would make it impossible. The opportunities and dangers of contamination in the preparation of a serum for intraspinal injection by an "open-air method" are manifest. Instruments, receptacles and appliances were above suspicion by reason of the effectiveness of modern hospital methods of sterilization. The skin of the patient at points of puncture, and of the hands of operator and assistant, cannot, however, be completely sterilized by any known method. Then there is the possibility that any open receptacle containing blood or serum may have a particle of foreign matter accidentally deposited in it by a gust of air, or the sudden motion of a garment or other fabric during even a brief exposure. It could easily carry many micro-organisms which might be pathogenic, and which during the hours that the ideal culture-medium stands, might produce a massive dose. Even though placed in a refrigerator, a procedure which might easily be somewhat delayed, sufficient chilling to produce effective inhibition might be long enough postponed to permit considerable germination. This may be a remote possibility, but it should nevertheless be removed. The paucity of antibodies in the spinal fluid points to a danger from the introduction of even a few attenuated micro-organisms which might be negligible in the blood with its ample protective resources. Without further preliminary discussion, the technic will now be described.

---

[1] McCaskey, G. W.: The Autoserosalvarsan Treatment of Syphilis of the Central Nervous System, The Journal A. M. A., Jan. 17, 1914, p. 187



Apparatus tor autoserosalvarsan treatment.

The apparatus consists of an inverted U-shaped glass tube, 1½ inches in diameter, each arm being about 5 inches long. One arm of this tube, *A*, is for the reception of the blood, the other, *B*, for the serum after its separation. The latter is graduated. The rubber stoppers *C, C'*, in each arm of the tube are held in place by metal plates, *D* and *D'*, passing across them, and fastened in their turn by fine copper wire to projecting glass hooks, *E*, on the sides of the tube. Through centrally placed perforations in the rubber stoppers and metal plates pass small pieces of glass tubing, *F*, and *F'*, which extend about 3 inches into each arm of the tube. To the small tube *F'*, projecting into the serum arm of the large tube, is connected a vacuum pump *G*, and to the other a needle suitable for puncturing a vein and collecting the blood. At *H* is interposed a small glass bulb containing cotton to filter the air which might be forced into the large tube if the vacuum pump failed to work properly. This outfit, connected as shown in the illustration (excepting that the vacuum pump is left out, because the steam ruins the washers) is properly wrapped and placed in a steam sterilizer and thoroughly sterilized.

When the operator is ready to proceed, the needle, which has been paraffined before sterilization and closed with a stylet, is introduced into a suitable vein, the *dry* skin over which has been painted with tincture of iodin. The vacuum pump is then operated by an assistant and the blood rapidly pours out of the top of the small tube *F* and falls to the bottom of the large tube. It is desirable to procure about 60 c.c. The vacuum pump is then disconnected from the cotton bulb, and air filters in to produce an equilibrium. If the needle is withdrawn from the vein first, *unfiltered* air would rush in, and might carry impurities. The needle is now removed, the bulb *H* transferred from *F'* to *F* and the connecting rubber tubes are covered with sterile gauze and rubber finger-cots, which are tied around the lower ends of the glass tubes.

The apparatus containing the blood is now placed in the refrigerator over night, and in the morning the quantity of separated serum desired is poured into the serum arm of the tube by simply tilting it toward that side. It is next placed in an oven and heated to 56 C. (132.8 F.) for thirty minutes, according to the Swift and Ellis technic. The serum is diluted with normal saline solution which has been placed in the graduated serum arm of the large tube before placing it in the sterilizer. The exact amount will depend on the dose and dilution of the serum which it is intended to give by the intraspinal injection. This must, of course, be determined in advance. For example, if it is desired to give 12 c.c. of serum in 40 per cent. dilution (as advised by Swift and Ellis), 18 c.c. would have been used.

The rubber tube (about 18 inches long and broken at two or three places by short pieces of glass tubing to be used as observation fenestrae), which is to convey the salvarsanized serum to the spinal puncture needle, is then connected to the glass tube *F'*, which is now pulled down until the upper end is flush with the inner surface of the rubber stopper. The serum is then allowed completely to fill this tube to its lower end, all air being, of course, excluded, when a suitable clamp, for instance, an artery forceps, is fastened over the rubber tubing *about one inch from its lower extremity*. This free end, which will remain filled with serum, is later to be fitted over the other end of the spinal needle from which *spinal fluid is emerging*. The clamping forceps are held by an assistant with *sterile rubber gloves*.

I then take the spinal puncture needle, with gloved hands, introduce it into the spinal canal, through skin previously painted with tincture of iodin, withdraw from 5 to 20 c.c. of spinal fluid, which is, of course, retained for laboratory study, and, while the spinal fluid is still flowing, connect the needle with the end of the rubber tube filled with salvarsanized serum.

The apparatus, held by another assistant, is then elevated. The serum usually flows in readily by gravity, but, if it does not, a pressure-bulb is connected with the small tube in the opposite arm and air pumped in through the air-filter, *H*, sufficient to produce any desired degree of pressure.

An aseptic gauze dressing over the puncture wound completes the procedure.

Repeated use of this apparatus has failed to show any defect from the points of view of asepsis, simplicity, cheapness,[2] or convenience. The rubber stoppers alone have to be frequently replaced to avoid leakage, which will occur as a result of repeated sterilizations by heat. With the use of aseptic gloves, the only possibility of serum contamination would be in puncturing the iodinized skin over vein or lumbar spine. If germs can be picked up by a needle in passing through iodinized skin, assuming this to be the best method, then a perfectly aseptic technic is, of course, unattainable. Such dangers are so remote that they can well be ignored in carrying out so effective a method of attack against a fatal disease, relatively immune against all other procedures.

II. TIME OF WITHDRAWAL OF BLOOD

According to the technic of Swift and Ellis, the blood is withdrawn one hour after the intravenous injection of neosalvarsan. If the purpose of the treatment is, either in whole or in part, the introduction of neosalvarsan into the spinal canal, such a delay appears objectionable, unless demanded by other considerations. Wechselmann[3] says that the Abelin reaction for salvarsan disappears in some cases in one hour. The amount of salvarsan in the blood undoubtedly diminishes rapidly from the moment of its injection. Of this fact, which could have been predicted confidently on purely biologic ground, I have fully satisfied myself by testing the blood at different intervals after the injection of the neosalvarsan.

In regard to the intraspinal dosage of neosalvarsan by the Swift and Ellis technic, what are the facts so far as these can be predicated? A full conventional intravenous dose of neosalvarsan contains 900 mg. The average human body is said by physiologists to contain about 3,000 c.c. of blood. A very simple calculation will show us that if this entire quantity of neosalvarsan is evenly distributed in the blood, each 12 c.c. of serum (the amount advised by Swift and Ellis) cannot contain more than $^1/_{250}$ of the entire dose, or 3.75 mg. Of course, in a very few minutes it will be much less, and continue to diminish until at the end of one hour it may not be detectable by the most delicate test.

In an effort to increase the intraspinal dose of neosalvarsan, I have gradually and cautiously shortened the time until now the usual routine is about twenty minutes after the completion of the intravenous injection. In order to secure more rapid uniform diffusion through the circulating blood, the neosalvarsan is injected very slowly, over a period of seven or eight minutes — the approximate time for the complete circulation of the blood. This insures a preliminary mechanical mixture or a general distribution throughout the blood mass, which would not occur if it were injected in one or two minutes. In fifteen or twenty minutes from the completion of the injection, I believe that uniform diffusion may be confidently assumed, and, as any one can easily satisfy himself by the Abelin test, the quantity of neosalvarsan in the blood at this time is several times greater than at the end of an hour.

There has not been, so far as I can determine, any more pain following the intraspinal injection of serum obtained in twenty minutes than with that obtained one hour after the intravenous injection of neosalvarsan. As a general rule, there is no pain of consequence following the intraspinal injection. Occasionally, immediately or even after from six to ten hours moderately severe pain may rather suddenly develop in back and limbs, lasting several hours. There has been no increase in the incidence or severity of this pain since shortening the interval between the intravenous injection and the bleeding.

Much of its therapeutic efficacy, however, may be attributed to the serum *per se* independently of its salvarsan content; the latter is after all the known specific spirocheticide, and I cannot avoid the conclusion that an intraspinal dose of serum containing perhaps between 2 and 3 mg. of neosalvarsan offers more therapeutic promise than one from which it has so completely disappeared as to be no longer demonstrable. I have, therefore, adopted, and advise a twenty-minute interval as above outlined.

III. DOSAGE AND DILUTION OF THE SALVARSANIZED SERUM

With a view of increasing, if possible, the intraspinal dosage and, therefore, the therapeutic efficiency of the salvarsanized serum, I have, again very cautiously, lowered the dilution until in a few cases undiluted serum was used. We found in the laboratory that the undiluted serum, which has a specific gravity of about 1.035, would rapidly settle to the bottom of a test-tube containing spinal fluid, which has a specific gravity of about 1.012. The rate of fall was almost exactly 1 cm. per second. Moreover, it tends to remain at the bottom of the tube a long time, diffusing through the spinal fluid very slowly. This might be imitated to some extent in the lower segment of the dural pouch, and might obviously be objectionable. In from 60 to 80 per cent. dilution, however, diffusion readily occurs. I do not, therefore, use and would not advise lower dilution.

I usually begin with about 15 c.c. of serum made into 50 per cent. dilution. If thought necessary in subsequent treatments, the quantity of serum is increased by varying the dilution without increasing the bulk of the injection. In some cases the original dose is not modified. In obstinate cases this can be done without any untoward effect so far as I can determine in the way of pain or other reaction and, obviously, offers a means of intensifying the therapeutic effect without increasing the bulk of the injection. Just to what extent this is desirable or justifiable is a question of clinical judgment in the individual case.

While it is not my intention, as stated above, to make a further detailed clinical report just at this time, a few words of comment may perhaps be added.

The necessity for and rationale of the treatment, as well as therapeutic results entirely unattainable by other known methods, are receiving additional confirmation with the passing months. One of the most interesting side-lights is contained in a recent contribution by Flexner and Amoss.[4] The experiments there cited, which consist of the intravenous injection of poliomyelitic cerebrospinal fluid, "afford valuable support," to quote the language of the authors, "to the hypothesis that infection of the nervous organs in man occurs through the mediation of the cerebrospinal fluid." To accomplish this transfer (that is, from blood to cerebrospinal fluid), time is required, *since the barrier of the choroid plexus must first be overcome.* At the expiration of forty-eight hours following the intravenous inoculation, the barrier appears still to be intact; at the expiration of seventy-two hours the passage of the virus seems to have begun, since infection of mild type followed the inoculation of the cerebrospinal fluid removed at this period. At the expiration of ninety-six hours, it appears that the barrier had broken down; and it also appears that under the pathologic conditions created, the virus, in quantity sufficient to cause infection, still persisted in this fluid as late as the nineteenth day, although no longer detectable in the blood by the inoculation test. I have several times found clinically what may, I think, be regarded as an analogous condition in *untreated* syphilis. The infection as determined by the Wassermann test had disappeared from the blood, but was still present in the spinal fluid. Such a condition is, of course, common in cases treated through the bloodstream alone.

---

[2] This entire outfit costs about $5. The vacuum pump is a staple in the market at $2. The U tubes can be made by any glass-blower for $2 or $3.

[3] Wechselmann: Salvarsan Fatalities.

[4] Flexner, Simon, and Amoss, Harold L.: Penetration of the Virus of Poliomyelitis from the Blood into the Cerebrospinal Fluid, Jour. Exper. Med., April 1, 1914, p. 411.

The modification of the spinal fluid Wassermann test during the progress of these treatments is extremely interesting and variable. It does not always proceed *pari passu* with clinical improvement. For instance, in one of my cases[5] under the care of Dr. Walter Domer of Wabash, Ind., the patient suffering from advanced tabes with great emaciation, complete urinary incontinence, both day and night, insanity of a very marked type requiring constant supervision and frequent restraint, etc., has gained 43 pounds in weight, *has regained control of the bladder during the day,* though he still has nocturnal incontinence, and has so completely recovered his normal mentality that he has resumed his usual occupation. The cerebrospinal fluid Wassermann, however, still remains positive, after eight intraspinal treatments.

In another case of advanced tabes with rapidly progressing disability, the spinal fluid Wassermann was practically negative after two treatments, although no clinical improvement could be noted. Sufficient time perhaps had not elapsed. On the other hand, degenerative changes in the nerve elements may proceed for a time even though the infection has been overcome; and in any event the restitution of these degenerated elements must for the present be considered entirely problematical. A great deal more time must elapse before we shall "get our bearings."

If the evidence thus far at hand, still further strengthened by these experiments, supports the assumption that "infection of the nervous organs in man occurs through the mediation of the cerebrospinal fluid," then obviously the most rational mode of attack, if practical, is through this same "mediation." It is equally obvious that the "lumbar route" offers at once the only safe and available method. That it is practical and therapeutically potential has been shown by the work of the Rockefeller Institute and the clinicians who have been guided by their researches.

The direct injection of a 6 per cent. solution of neosalvarsan into the spinal canal, which is practiced by Dr. Ravaut at Paris and to which attention has been recently called by Wile,[6] does not appear to me to offer the same advantages as the Swift and Ellis technic. The latter observers have warned us of the actual danger in the use of these injections, their warning being based on experimental work with monkeys. This warning should not pass unheeded. Aside from this, however, the practical simultaneous use of the intravenous and intraspinal injections offers a combined attack on the blood and lymphatic side of the infection at every point. Then again the serum introduced into the spinal fluid may readily be assumed to contain important antibodies which may play a large rôle in the therapeutic result. This is especially plausible, because it is quite in line with the well-known facts in regard to the relative amount of antibodies in these two fluids. If it can be demonstrated that the Ravaut method is safe, it might be used to supplement the Swift and Ellis method and avoid too frequent and too intensive intravenous dosage with neosalvarsan.

I wish to express my indebtedness to my clinical assistant, Dr. Miles F. Porter, Jr., for his aid in this work.

CHRONIC DEMENTIA, CEREBELLAR ATAXIA, AND EPILEPTIFORM CONVULSIONS IN A BOY CAUSED BY PTOMAIN POISONING FROM EATING CANNED SALMON *

CHARLES W. BURR, M.D.
Professor of Mental Diseases, University of Pennsylvania
PHILADELPHIA

We know little about the direct immediate cause of dementia save in cases associated with visible disease of the cerebral arteries, paresis and senile dementia. Dementia in children has been largely neglected. Persons who are born defective or who become so in childhood we are too prone to classify as idiots or imbeciles and then, so far as study goes, forget. Many of the latter are really suffering from a dementia resulting from an acute acquired insanity. In every asylum for the feeble-minded there are a large number of patients the cause of whose mental illness is unknown, and who, in accordance with the severity of the mental defect, are classed as idiots or imbeciles; those bereft of reason being called idiots, those having some mental power, imbeciles of higher or lower grade. It would be better, as has been suggested by European writers, to use the word "idiot" to include those persons who are suffering from the results of intra-uterine physical disease or accident at birth or illness soon after, without regard to the amount of mental defect resulting, instead of following the present classification, which is purely arbitrary and based on the amount of mental defect no matter what the cause. Under such a classification, the word "imbecile" would mean any person who, on account of inherent weakness, and not from physical disease or trauma early in life, for instance, scarlet fever or a serious concussion of the brain, ceases at any time to develop mentally and then retrograde. Such children differ qualitatively as well as quantitatively from idiots. Of course, there must be some underlying physical defect in them, but it is part of their inherent nature and not the result of accident or acquired disease. The cause probably is often outside the brain itself. Hypothetically, the condition may be explained by abiotrophy, a term introduced by Gowers to explain certain muscular dystrophies in which he assumes an inherent weakness of the muscle-cells which causes them to degenerate under the ordinary stress and strain of life without the increased strain of illness, trauma, or severe emotion. It is possible that this inherent, congenital weakness may occur in the brain-cells in certain persons and result in imbecility. It is a matter of indifference whether the abiotrophy is so great as to prevent any mental development or only sufficient to cause a breakdown later. Another possible explanation is a disorder of one or another of the ductless glands, or a disturbance of the balance between them. Our knowledge of the function of these glands is, however, so fragmentary that it is dangerous to attempt to draw any general conclusions. That disease of one of them may lead to very serious mental trouble is shown in cretinism, which, as is well known, is due to disease of the thyroid. The curious mental state, not very infrequent in Graves' disease, may also be due to thyroid disorder. The hebetude, or at least, if that be too strong a term, the extreme mental slowness, present in almost every case of acromegaly may be either directly caused by disturbance in the function of the pituitary gland or due to the mere mechanical effect of pressure of a tumor of the brain. Our knowledge of the functions and diseases of the ductless glands is still very hazy, but it may, in the future, be proved that the disorder in their functions accounts for some of those people who break mentally in childhood without external cause and without visible cerebral lesion. A very striking difference between idiocy and imbecility, as here defined, is the fact—and I am convinced that it is a fact—that heredity plays relatively little part in the former (idiocy), and a very large part in the latter (imbecility). I have seen many idiots in whose family history I could discover no mental taint. Thus all three children in one family were idiots, not from heredity, but from injury at birth, due to pelvic deformity in the mother. Congenital syphilis, which is not hereditary in the proper sense of the word, also causes idiocy. Almost every imbecile, on the contrary, whose ancestral history I know, came from a family showing a vicious mental strain, either insanity itself, hysteria, epilepsy, extreme eccentricity, or alcoholism, which is itself more often a sign than a cause of illness. By "strain" I do not mean the sporadic occurrence of any of the above-named states in a family, but the repeated appearance of one or several in a family generation after generation.

---

[5] *Case 4 in my previous paper (Footnote 1).*

[6] Wile, Udo J.: The Technic of the Intradural Injections of Neosalvarsan in Syphilis of the Nervous System, The Journal A. M. A., April 11, 1914, p. 1165.

* Read at the meeting of the Philadelphia Psychiatric Society, May 8, 1914.

Whatever may be the cause of imbecility, there is still another class of patients, though in the asylums all these are frequently classed together in one group, because the final picture is the same. They are the juvenile dements: people who in childhood present no abnormalities, either mental or physical, and who may have a fairly good ancestral history, but who, after some acute disease, or even in its absence, become demented. The dementia may follow any of the acute infectious fevers—scarlet fever, pneumonia, influenza—just as it may follow infection in adults, or may come on idiopathically. I am inclined to believe that the number of juvenile dements is very large and that true imbecility is less frequent, but it is almost impossible to get correct histories from families who, several years after the illness has begun, send their children to institutions, and for this reason statistics are very faulty.

I shall relate in this paper the history of a boy patient whose dementia is due to a very rare cause, namely, food poisoning. Medical literature is full of detailed accounts of the acute mental symptoms of ptomain poisoning, but I have found no description of chronic cases.

Family History.—There was nothing very striking in the patient's family history except that his father was one of those men who are continuously and uninterruptedly unsuccessful. He was industrious and honest, religious in a sane way, very temperate, but he could never find his niche in the world. Wanting to be thrifty, he was always thriftless and the responsibility of caring for the family rested largely on his wife—a state of affairs which, to reactionaries and conservatives, points toward mental insufficiency on the man's part. This, however, was the only black spot in his character, and to moderns and the disciples of feminism it would look only a very light pearl gray, pretty rather than hideous.

Present Illness.—The boy himself was an ordinary boy, neither good nor bad, neither brilliant nor dull. He was one of five children and had never had any serious illness until he was 14 years old, when the present illness began. Oct. 24, 1909, while at boarding school, he, along with twenty other boys, ate canned salmon. All, in a few hours, became very ill with symptoms of fish poisoning and, several (I think three but I am not sure of the exact number) died. My patient survived but was bed-ridden for some time. Indeed, he had a fever continuing several months. During this time he had a transient hemiplegia, several general convulsions and bed-sores. At times he was delirious. One of the most striking incidents was that, beginning about eighteen months after the onset of his illness, his usually dull and stupid state was occasionally replaced suddenly by an acute delirium lasting from two days to two weeks. He never had any recollection of these delirious attacks. He also continued to have occasional convulsions about once a month though sometimes the interval between was longer. Frequently an attack of delirium followed, but according to the history either might occur independently of the other.

Examination.—My own first examination was made on April 3, 1911, a few days after the beginning of one of the attacks of delirium. I found the patient in bed, ill nourished and with a skin of the dirty yellow-white of half-dried flour-paste. He rambled continuously in his talk, his mind dwelling on love and religion. At times he was profane and obscene. He answered two or three questions as to his name and dwelling-place but beyond that paid no attention to what was said to him. He had no realization of his condition, nor whereabouts. He was foolishly happy, not violent but restless, tried to get out of bed but merely putting a hand on his shoulder caused him, for the time, to cease his efforts. There was no palsy in any part but his gait was very ataxic—a true cerebellar ataxia. In bed he moved his legs well. His knee-jerks were normal. There were two large scars of old bed-sores on the sacrum. He paid no attention to his bladder or rectum. He drank his milk (he was on a milk diet) voraciously but never asked for food. The transient hemiplegia mentioned in the history had passed away entirely and left no marks of its presence.

Course.—He continued in the hospital till June 27, 1911, when I sent him to a suburban rest-house. While in the hospital he had a number of fleeting visual and auditory hallucinations. For the most part they were really illusions—the false interpretation of things seen or sounds heard. Some, however, seemed to be true hallucinations—to have their origin within himself and not externally. He improved quite a little by June and presented the picture of a dementia plus cerebellar ataxia. His gait was made somewhat curious by the fact that, having been a student in a military academy in the South, he seemed to have exaggerated the stiffness of the military attitude so that his gait was a mixture of strut and ataxia. On turning he tended to fall but always recovered himself. He stood with the feet wide apart. His station was not bad and was not made more unstable by closing the eyes. There was a little ataxia in the hands. The knee-jerks were very much increased. There was good control of the bladder and rectum. Articulation was good. The patient had no recollection of having seen me before though I had visited him a dozen times, the last visit having been three weeks before. He had no delusions or hallucinations. He understood simple conversation and answered intelligently, but his mental development, that is, his power of reasoning, so far as we can measure abnormal states with the yardstick of normality, was about that of a 9-year-old boy. He was contented, happy and well-mannered.

On July 6, 1911, the patient walked a little better but was still very ataxic. It was very difficult for him to turn without falling. The knee-jerks were normal. There was no ataxia in the hands. He understood what was said to him and answered questions responsively. His memory for recent events was very poor. He could tell accurately about events of his childhood but he had no recollection of having been seriously ill. He remembered vaguely that while at school he had had some sort of an illness but remembered nothing of its nature; indeed, I am not sure whether he really remembered being ill or only remembered being told that he had been so. He had no recollection of having been brought to Philadelphia from a Southern city, some months before, and did not remember anything about being in the hospital or ’out being sent to the country. He thought he had seen me newhere but was not sure. He was happy, good-natured nd easy to control but rather silly. He cared neither to read nor to be read to. He ate and slept well.

By Aug. 24, 1911, the patient's speech had become slow and drawling. His memory was a little better. When he went to the country he had forgotten how to use a knife, fork and spoon, and frequently even tried to eat soup with a fork. Meal after meal he had to relearn experimentally how to use table-ware. It took him several weeks to learn where his bedroom was and how to go to it from down stairs. These symptoms had passed off by now.

By Sept. 27, 1911, he began to have attacks of headache, at times so severe as to send him to bed. He also was occasionally nauseated but never vomited. His knee-jerks were again increased. He never complained of vertigo.

Oct. 15, 1911, his memory for the geography of the house again became very bad. He knew it was a house, that he was living there, that there were people there to care for him. He recognized the people and remembered their names, but he could not remember how to go from any room on one floor to any room on another. He recognized his own bedroom when within it but when in the hall could not recall which of several doors opened into it. This loss of geographic sense was not confined to the inside of the house. He was lost as soon as he was out of sight of it. This cannot be explained by a dement's mere inability to fix attention and a consequent absence of memory, because by now he remembered people seen and things told him fairly well and, therefore must have had some real power of fixing his attention. He could remember a short story for children.

Between Nov. 18, 1911 and March 4, 1912, he had two general convulsions and five attacks of unconsciousness, lasting from one to several hours, without a preceding visible convulsion. During these attacks of unconsciousness he sat inert, gazing into space and could not be roused. He recovered consciousness slowly and then usually complained of headache. In addition to the convulsions he had many attacks of minor epilepsy. I am inclined to believe that the long periods of unconsciousness really followed attacks of petit mal.

In February, 1912, the patient began to grow in height very rapidly. Previously there had been no growth since coming to Philadelphia. Anatomic sexual development was normal but he was functionally apparently inert. His growth continued during his stay North and has not ceased since his return home.

Examination of Eyes.—Dr. H. Maxwell Langdon examined the eyes in October, 1911, and reported: "Vision in the right eye 6/8, vision in the left eye 6/10. Pupils equal and normal, ocular rotations full and equal, no diplopia. At the limits of lateral excursion there develops a fine tire nystagmus. The media are clear, the disks very pale, with sharply defined margins. No other fundus lesion. The visual fields go well with the atrophic nerves except for the homonymous cut in the upper left field, which strongly suggests a lesion posterior to the chiasm, either an organic exudate or hemorrhage. The optic atrophy is apparently a primary affair—I mean, has not followed an optic neuritis; it may have descended from a lesion higher up in the optic tracts."

Immediately before the patient returned to his home, in the early summer of 1912, his condition was the following: Marked cerebellar gait. Knee-jerks marked. No ataxia in arms. No palsy in arms or legs. Speech slow and drawling. Memory for passing events much improved but still poor. Power of attention poor. Read a little. Wrote short and childish but coherent letters. Liked to play with children. Polite in manner. Disposition good. Geographic sense recovered. He continued rarely to have severe general convulsions and quite often minor attacks, but his attacks of long lasting unconsciousness ceased to occur several months before leaving Philadelphia.

When I last heard of the patient a few months ago he was somewhat better. He cared more for reading and read more mature books. He talked less like a child. His ataxia continued. He undoubtedly was quite demented, though to his mother's eyes he had improved greatly.

The case has many points of interest. First, as to the naming of the mental condition. Should we call the boy an imbecile or a dement? In view of his history, he is of course a dement, but if he were to be seen now by one who knew nothing of his past I think he would be classed as a rather high-grade imbecile with some intercurrent organic nervous disease. There is no way to tell, from a mere examination of a boy free from physical defect, whether he is one or the other. Yet for scientific purposes it is important to keep apart children who break from inherent weakness and those who require a serious stress to overthrow their mentality.

I have been unable to find any case with a similar cause in the literature. I do not say others have not been reported, because my experience has been that as soon as one claims uniqueness in a patient in print, similar cases, previously hidden in obscure journals or forgotten proceedings of societies, come to light. It must, however, be extremely rare, as its possibility is not even mentioned in the text-books. A rather large number of cases of acute delirium from food poisoning are recorded, but the patients either died or soon recovered. That salmon poisoning was the cause in this case there is no doubt. The history proves it. The only possibility of error would be the simultaneous occurrence of two illnesses, the poisoning plus, say, cerebral syphilis. The latter, however, can positively be excluded.

The combination with dementia of physical symptoms referable to the cerebrospinal axis and surely due to gross organic disease is, in persons so young, very rare. In many ways the case clinically resembles juvenile paresis. The dementia, the drawling speech, the silly happiness, without, however, any distinct delusion of grandeur, the ataxia, the (for a time) increased knee-jerks, the epileptiform convulsions, all make the picture of paresis. The factors in the case against its being paresis are the absence of congenital syphilis (every case of juvenile paresis I have ever read of or seen occurred in youths with a history of parental syphilis), the very rapid onset, and the seemingly permanent improvement coming on slowly and extending over a length of time greater than that of a remission in paresis. This partial cure I emphasize because I cannot conceive, in the present state of therapeutics, of even a partial permanent cure of true paresis. I do not think that the absence of syphilis is of so much importance, because I can well believe that some other intoxication might affect the brain precisely as syphilis does. The case in no way looks like dementia praecox unless that much-abused term is to include all kinds of insanity that attack the young.

The patient's isolated loss of memory for places was most unusual. At a time when his memory for faces was fairly good and when he could remember things told him quite well, he could not learn the geography of the house and surrounding fields. Of course, it requires more fixity of attention to learn a house than it does to listen and fix in memory a thing said, but it seems to me that lack of attention does not explain the condition. The patient seemed to have a local memory loss comparable to amnesia for words.

That there is a real organic lesion present I think is sure. I fancy the patient has a pretty wide-spread cortical lesion affecting most markedly the intellectual centers and the cerebellum and probably primarily attacking the nerve cells rather than the arteries. The long continuance of the illness, together with the character of the symptoms, is against a merely functional disorder and the optic atrophy is positive evidence of organic disease. I think we may assume that the optic atrophy is a visible sign of similar changes in the brain itself.

1918 Spruce Street.

PREGNANCY AND LABOR COMPLICATED BY CARCINOMA OF THE CERVIX UTERI

ROBERT YOUNG SULLIVAN, M.D.
Associate Gynecologist to Providence Hospital, Washington, D. C.
WASHINGTON, D. C.

Cancer complicating pregnancy and labor is of such rarity and the calamity of such a complication is so grave that it excites the deepest interest and attention.

De Lee and Hirst, each quoting the statistics of Sarwey and Kerr cite twenty-six cases occurring in fifty-seven thousand pregnancies, or approximately once in every two thousand pregnancies. This ratio is accepted by Edgar, Williams, Ashton and others. De Lee also cites a series of fifteen thousand consecutive maternity cases occurring in the Chicago Lying-In Hospital with only one case of cancer of the uterus arising as a complication. Since these patients were of the usual social standing of the average private practice he thinks this is a fair estimation for such an occurrence in private practice. It is evident by referring to the statements of such standard authors that the condition is more often seen in the cases in the charity wards than in private practice. It is noteworthy that in America this condition is more frequently found among the immigrant strata and among negroes than among American-born white persons. The relatively small number of such cases is evident when men of large experience in the city hospitals have never seen a case.

On account of the environment but little information can be obtained regarding the course of pregnancy, especially during the early months. It is evident, however, that the advent of pregnancy greatly favors the inroads of cancer, when they coexist; during gestation and the puerperium the progress of cancer is astonishingly rapid, especially in the latter period. Because of the influence of pregnancy an enormous increase in the blood-supply of the uterus occurs, inviting rapid infiltration and metastasis, while during the puerperium rapid necrosis takes place.

It is impossible to accurately estimate the death-rate in this condition, but it is believed to be nearly 100 per cent.; a cure being a most unusual triumph. Edgar, in discussing this subject, says that in 15 per cent. of such cases miscarriage occurs before the period of viability, and that in 33 per cent. of the remainder the children die during labor or shortly afterward.

The course of labor in the cases complicated with carcinoma of the cervix is attended with grave danger. If left to the natural course, death from hemorrhage of the friable but resisting lower uterine segment is very probable. The anemia, as well as the uterine infiltration, greatly predisposes the patient to general and local inertia; ultimately death ensues from shock, hemorrhage and sepsis. The course of labor is prolonged, often continuing several days; it is ineffectual in its mechanism, owing to the undilatable cervix and inefficient pains; it often terminates in the rupture of the uterus or maternal death from shock while still undelivered.

When there is a bare possibility of effecting a cure of the cancerous condition complete hysterectomy should be done as early as possible. The interests of the mother are to be considered whenever there is a reasonable hope that a cure may be effected and the Wertheim operation performed, regardless of the stage of gestation. Should the case be hopeless, so far as the interests of the mother are concerned, the welfare of the child is to be made paramount and an attempt made to reach the latest period in the course of pregnancy. This position is the consensus of opinion of both operators and authors.

At the end of the gestation period abdominal cesarean section with complete hysterectomy is the most popular treatment when it is hoped that both mother and child may be saved. In the cases in which the mother is beyond help abdominal cesarean section followed by complete hysterectomy when possible, or extraperitoneal treatment of the cervical stump after the amputation of the uterine body seems to be the most popular view at present. Ashton advises the amputation of the uterine body above the cervix in such cases and closes as in supravaginal hysterectomy for the purpose of closing off the cancerous mass. Duhrrsen recommends vaginal cesarean section, saying that it can be done as late as full term, delivery being followed by complete hysterectomy by the vaginal route.

It would seem that the control of hemorrhage, sepsis and shock would be more perfect by abdominal cesarean section and the chances of the infant greatly increased, while by natural birth or operative delivery by the birth-canal both mother and child would be more exposed to danger.

REPORT OF CASE

Mrs. I. D., a well-nourished Italian woman aged 34, housewife. Family and previous histories negative.

Genital History.—Menstruation began at 14 years and until what seemed to be the beginning of the present illness was always regular in time, quantity and duration. Menstruation was slightly painful, periods lasting from three to four days and were moderate in amount. Patient married in 1903. Since that time there have been four pregnancies to the present illness, all terminating normally at full term; no miscarriages.

Present Illness.—This patient was first seen by me in consultation with Dr. Mary Holmes on April 22, 1913. She then complained of severe aching pain in both tubo-ovarian regions. For a period of two months there had been loss of flesh and strength with continual headache and backache. There had been urinary tenesmus, dark, bloody, foul-smelling vaginal discharge extending over a period of three months. At various times she had lost considerable blood from the vagina.

Examination.—Chest normal, abdomen enlarged symmetrically, showing presence of old and new striae. Fetal parts and fetal heart-sounds were easily made out, the heart beating at the rate of 120 beats per minute. The position was left occipito-anterior. Fetal motion was perceived. The infant was vigorous and had apparently reached the sixth month of gestation. Vaginal examination at that time revealed foul-smelling bloody, purulent discharge. The cervix was large, elongated, hard, nodular and bled very freely when touched. A portion was examined microscopically and found to be carcinomatous. It was also evident that the case was one of advanced carcinoma, since there was fixation of the uterus and vaginal infiltration. So far as a radical cure was concerned the case was hopeless. The blood-pressure was found to be 100 mg. and the hemoglobin estimated at 80 per cent.

The diagnosis of cancer and pregnancy was made and the interests of the infant made paramount. Every effort was made to forestall premature labor in the hope that cesarean section would deliver a living child if an advanced stage of pregnancy could be reached.

The patient was put to bed, given morphin liberally, encouraged to take nourishing food and given salt solution by the bowel daily. On June 12, 1913, labor ensued at approximately the thirty-second week of pregnancy and after a few hours the patient was exhausted by the pains and shock. Since no progress had been made in dilating the cervix cesarean section was advised and performed as soon as the patient could be transferred to the Columbia Hospital for Women. At the beginning of the anesthesia the baby's heart could be faintly heard, but in spite of rapid delivery it was still born, much to our regret.

Amputation of the uterus above the cancerous mass involving the cervix was done and it was planned to treat the cervical stump extraperitoneally. It was possible to do this, since the cervix could not be lifted out of the pelvis and could not be attached, so great was the infiltration and necrosis of the tissues. Closure in the usual method, as in supra-vaginal hysterectomy, was made after the cervical stump was thoroughly painted with full strength tincture of iodin. There was little hemorrhage, the abdomen was closed without drainage and there was no sepsis or wound infection.

Most extensive evacuation of the vaginal vault followed in spite of actual cautery with the angiotribe. The patient died six weeks after operation. She was out of bed but her failure in general ways was excessively rapid.

I believe that such cases can be safely closed by removing the body above the cancerous mass, thus doing away with the uterus that invites further extension and contamination. It is possible in this way to close off the necrotic cervical stump with pelvic peritoneum as in ordinary incomplete hysterectomy. By operating as soon as labor was evident, before shock had occurred and the patient thus exhausted, it is possible that this baby could have been saved; since it had always been vigorous until the day of operation. Abdominal cesarean section evidently was the only possible means of delivering this infant alive.

I am grateful to Dr. I. S. Stone for his advice and also to Dr. Mary Holmes for the courtesy in allowing me to see this patient.

The Burlington.

PARAFFIN CANCER

COAL AND PETROLEUM PRODUCTS AS CAUSES OF CHRONIC IRRITATION AND CANCER *

BENJAMIN FRANKLIN DAVIS, Ph.D., MD.
Nicholas Senn Fellow in Surgery, Rush Medical College
CHICAGO

It is customary to include in any summary of the causes of cancer the blanket term "chronic irritation." Prominent under this heading are the inflammations peculiar to the influence of tar, paraffin, anilin, tobacco and soot; lupus vulgaris (a small proportion) and other types of cutaneous tuberculosis; ulcerating syphilis, rarely; irritated warts and pigmented moles; cicatrices, especially from burns or chronic leg-ulcer; circumscribed keratoses — cutaneous horns — callosities, palmar and plantar arsenical lesions; leukoplakia buccalis and lesions in the neighborhood of jagged teeth, senile keratomas.[1] Hyde[2] mentions exposure to sunlight, while the almost mathematical certainty with which cancer may be induced by the Roentgen ray has become a matter of common knowledge.

The dermatitis resulting from paraffin irritation was first discussed at length by Volkmann,[3] who distinguishes an acute and a chronic stage. The acute stage expresses itself in various eruptions that are at times acneform and at other times exhibit broader papules. In other cases there are severely inflamed, partly confluent nodules and boils. But few workers in the fluid products in the manufacture of paraffin escape this condition. The acute stage lasts several months, and then the skin becomes accustomed to the contact of the aforesaid material so that the severely inflamed, moist and itching skin-changes no longer develop. Instead there now developes an increased formation of epidermis with an exaggerated secretion of the oil glands. The papules, boils and nodules shrink and form flattened, psoriasis-like spots with here and there rust-colored pigment spots. They may likewise leave behind whitish scars. The skin becomes dry, parchment-like or scaly and fissured. The hyperplastic epidermis cells lead to the formation of either circumscribed or more diffuse horny thickening. Mixed with a lesser or greater amount of sebaceous secretion, they form seborrheic plaques and crusts. Volkmann compares their appearance with hardened wax drops. When abundant they may present a resemblance to ichthyosis. The skin affection has been called "tar itch" by workers in this material. With the further development of the disease there develop multiple warty growths which later singly or in numbers degenerate into carcinomas. This final stage is described by Volkmann as follows:

---

* From the Surgical Clinic of Dr. Arthur Dean Bevan, Rush Medical College.

[1] Hartzell: Jour. Cutan. Dis., 1903, xxi, 393.
[2] Hyde: Am. Jour. Med. Sc., 1906, cxxxi, 1.
[3] Volkmann: Samml. klin. Vortr. (Volkmann's), 1875, i, 370.

As a result of individual predisposition and particularly deficient cleanliness, the process, which previously has been a hyperplastic epidermic growth and sebaceous secretion, now develops into multiple, warty or papillary formations, some of which degenerate into cancer. In some cases the sebaceous crusts described above exhibit almost a horn-like consistency. The chief seat of these hyperplasias are the exposed forearms and the scrotum. In an old workman Volkmann counted fifteen such warty growths with thick crusts on the dark-brown spotted and fissured forearm, and three on the scrotum. This picture of warty growths completely suggests the "verruca cancerosa" of the aged.

Schamberg[4] tabulated the reported cases of cancer in tar and paraffin workers up to 1910 and remarked on their frequent tendency to undergo spontaneous involution. Many of the lesions ulcerate and destroy themselves. Of 27 cases described occurring among 18 paraffin workers, 6 workers in fluid tar and 3 employees in coal briquet factories, the lesions were on the scrotum exclusively in 8; on the scrotum and thighs in 3; on the scrotum and arms, hands, legs or face in 7; in 9 the scrotum was not involved, the lesions being distributed on the arms and hands in 7, on the face in 1, and on the face, back, arms and hands in 1. In 13 the lesions were multiple and so situated as to render auto-inoculation, or growth by metastases, as an explanation of this multiplicity, unlikely. There were 7 deaths reported, 2 due to recurrences after operation and 4 recoveries. The final outcome in the remaining 16 was not stated. Metastases occurred late in the disease and were usually lymphatic.

The source of the tar seems to be of great importance from the point of view of its power to damage the skin of workmen. In Great Britain "gas-works tar" as a rule produces dermatitis with the accompanying danger of malignant degeneration, while "blast-furnace tar" does not.[5] One explanation of this difference, experimental demonstration of which has been offered, is that "gas-works tar" contains substances which are capable of inducing cell division *in vitro*, and of causing the production of tumor-like masses in experimental animals, while "blast-furnace tar" does not. Pure paraffin apparently is not concerned in the production of cutaneous abnormalities, but the irritating substances seem to be present in crude paraffin as bodies having possibly an amidin $(N - C = N)$ nucleus, and associated particularly with compounds of the anthracene group. The greater portion of them are separated from paraffin probably with the thick, heavy oil analogous to the "pressed distillate" to be described later.

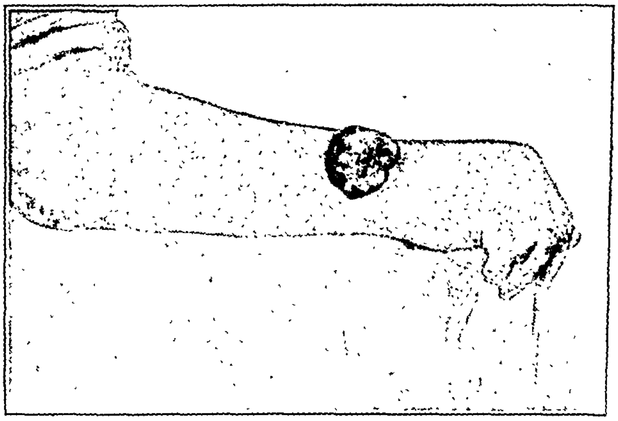
Study of the case which I wish to report through the courtesy of Dr. Arthur Dean Bevan reveals the following facts:

History.—The patient, A. P., man, aged 52, married, Hungarian, a laborer, entered the Presbyterian Hospital on the service of Dr. Bevan in March, 1913, at which time the following notes were made:

"A. P. is the oldest of thirty-two employees in the paraffin-refining department of a large oil-refining company located near Chicago. He states that after working in the refining department for a while all the workmen develop an eruption on the skin of that part of the arms which is immersed in the oil. The skin becomes slightly discolored, pigmented and thickened in circumscribed regions, sometimes to the extent of forming warty excrescences. One such growth on the patient's arm has been gradually increasing in size for the past two years until at present there is a cauliflower-like excrescence on his right arm just above the wrist, about the size of a silver dollar. Usually the patient has been able to abort such growths by the use of home remedies, but this one has resisted all his efforts.

"A. P. has been employed for over twenty years in the same department, longer than any one else, and only one other employee has at the present time a growth which resembles his. Except for this the patient is well.

"*Physical Examination*.—On the posterior aspect of the right forearm just above the wrist is a round, elevated, ulcerated, cauliflower-like growth. It is not painful or tender, and is about the size of a silver dollar. The skin of both forearms is slightly pigmented and is curiously mottled with regions that are brownish in color, slightly elevated, somewhat rough to the touch with a tendency toward scaling, and varying in diameter up to 7 or 8 mm. There are no other abnormalities.



Appearance of gross lesion in paraffin cancer; note mottling of the forearm.

"A section taken from the tumor and stained presented the picture of a typical epithelioma with pearls.

"*Operation*.—March 6, 1913, an oval incision was made about the epithelioma down to the muscles, and the tumor with the adjoining skin and fascia was removed in one piece. Thiersch grafts were used to cover the defect. The wound was dressed with gutta percha strips and gauze. The patient was discharged on the twenty-third day with wound completely healed. There was no sign of recurrence when the patient was seen six months later."

Investigation at the oil company's plant disclosed conditions about as follows:

Skin lesions attributable to their occupation were found only in the men employed in the press-rooms. Here the crude paraffin is run into great presses and the oils, "pressed distillate," expressed. The paraffin remaining in the press, so-called slack wax, is scraped off by men who use spade-like instruments and usually work bare-handed with sleeves rolled up above the elbows. During this process the workmen become pretty thoroughly smeared with the pressed distillate. The work is done at room temperature. During the first few months of employment in this department the majority of the workmen suffer from "wax-boils" affecting any portion of the skin, but particularly the arms and neck. The susceptibility to this trouble, which appears to be a species of furunculosis, may disappear in time to a very large extent. A certain proportion of the workmen, however, will develop still further lesions. Thus after a number of years pigmented spots make their appearance; some of these are scaling and psoriatic, others merely rust-colored areas varying in diameter from a few millimeters to a centimeter and a half; these may be followed by wart-like growths of slow development amenable to various common remedial measures; finally, true epithelioma, as in the patient A. P., may appear. These changes are seen only in those employees who come into intimate and nearly continuous contact with the "pressed distillate" for a period of years. Wax-boils and the subsequent lesions are unknown among the workers in the finished paraffin and among the men who handle the crude oil.

---

[5] Ross, Cropper and Ross and Associates: Researches into Induced Cell Reproduction and Cancer, and Other Papers, 1911, i, 1912, ii, and 1913, iii; the John McFadden Researches.

Inquiry at two other paraffin-refining plants, one at Cleveland and the other at Franklin, Pa., revealed conditions similar to those at Chicago, with the exception that less than 1 per cent. of the employees were said to be affected at all, and no cases of cancer had been observed. One manager says:

> In this connection, however, I would state that by the present methods of handling paraffin the men do not come as much in contact with it as they did years ago by the old process. Formerly there were a great many men employed at this work who suffered considerably from wax-boils.

Another writes:

> It is our general belief that if the men are perfectly clean, that is, wash themselves carefully after they finish their work, they never have any trouble.

A request for information as to the chemistry of the pressed distillate brought a reply from the chemists of the oil company, which is here quoted in part:

> Very little is known of the scientific chemistry of the oils you mention. Of course, we know a great deal about how they behave in a practical way. Generally speaking, I would say that 90 per cent. of this oil is composed of completely saturated members of the paraffin series C_nH_{2n+2}. Such bodies are perfectly inert and could not be active from a physiologic standpoint. The other 10 per cent. is composed of unsaturated bodies, perhaps of the series C_nH_{2n} and they could act as irritants or in some other way be detrimental to a person's health.

Attempts to induce tumor-like lesions in animals by the use of "slack-wax" and "pressed distillate" have so far been unsuccessful.

Closely allied with the subject of tar and paraffin cancer are the cases of tobacco cancer, cancer in workers in anilin dyes, chimney-sweep's cancer and the so-called kangri-burn cancer of India.

TOBACCO CANCER

In 1850 attention was directed to tobacco cancer by Melzer,[6] who reported on the incidence of cancer at the General Hospital at Laibach for the years 1787 to 1849, inclusive. Of the 27,800 patients treated, 433 had cancer; of these, 142 were on the lip. The patients were all in late adult life; 127 were men, 15 were women. These people were in the habit of smoking wooden, copper-sheathed pipes, with stems so short — not over 2 inches in length — that when in use the bowl of the pipe came almost into direct contact with the lips of the smoker. Melzer felt that the connection between the use of this pipe and the cancer of the lip was obvious. Of 350 cases of cancer of the lip in which operation was performed by Sir Thornley Stokes,[7] only three were in women, but all were assiduous smokers. These patients were peasants from the west of Ireland, and Stokes believed that their use of short clay pipes was directly associated in a causal manner with the production of their cancers.

A good deal of emphasis has been placed on the fact that cancer of the upper extremity of the digestive and respiratory tracts is predominatingly a disease of the male sex — the sex that is especially addicted to the use of tobacco — and that this is the location at which one might expect the lesions resulting from the use of tobacco to manifest themselves. Russell[8] points out that the incidence of cancer of the jaw and especially of the tongue increased 228 per cent. in forty-one years, while the habit of smoking more than doubled during the same period. In Switzerland during the years 1905 to 1909, cancer of the lip was five times more frequent in men than in women; cancer of the tongue, ten times more frequent in men, and cancer of the larynx, parotid gland and pharynx seven times more frequent, while the total mortality of the two sexes from cancer was almost equal.

Leukoplakia buccalis is usually the first evidence of the harmful local effect of the use of tobacco, and conversely, excessive smoking—according to Pusey[9]—is perhaps the most important source of irritation in producing the leukoplakia. "The condition is without subjective sensation. Its importance lies in the fact that it is very frequently the site of cancerous degeneration."

The substances in tobacco which act as local irritants predisposing to cancer are probably not confined to the smoke, but also appear to be present in tobacco-juice. Von Esmarch[10] in 1873 remarked that the cases he had observed of severe papillary cancer of the mucous membrane of the mouth and of the gums in youthful subjects had occurred in those who chewed tobacco, and von Langenbeck[11] mentioned two cases of cancer of the buccal mucous membrane, due to holding masses of tobacco against the cheek.

Tobacco is one of the important constituents of "betel-nut," which is chewed so extensively by the inhabitants of various tropical countries.[12] The betel-nut, more properly called the areca-nut, is produced by the areca palm.[13] The nuts grow in clusters beneath the crest of the palm, in a similar manner to the cocoanut. Areca-nuts are very similar to large nutmegs, both in size and appearance, and, like cocoanuts, are enclosed in an outer husk of a fibrous texture. "The consumption may be imagined when it is explained that every native (of Ceylon) is perpetually chewing a mixture of this nut and betel leaf. The betel is a species of pepper, the leaf of which very much resembles that of the black pepper, but is highly aromatic and pungent. . . . To make a 'chew': Take a betel leaf, and on this spread a piece of chunam (lime made from burnt coral) as large as a pea; then cut very thin slices of areca-nut and lay them in the leaf; next, add a small piece of ginger; and lastly, a good sized piece of tobacco. Fold up this mixture in another betel leaf." Cancer of the cheek is common among these people, the lesion appearing at the point against which the betel "cud" is habitually lodged. In the hospitals of Madras during the years 1892 to 1901, inclusive, 4,270 malignant tumors were observed,[8] constituting 2.5 per cent. of the total number of hospital cases. In nearly one-half of the cases the site of the cancer was the mouth or tongue of patients who habitually chewed "betel-nut." Dr. G. G. Davis, in a personal communication, says that he finds a high incidence of mouth cancer among Filipino betel-nut habitués. Baker[12] supposes the disease to result from the irritation of the caustic lime which the "chew" contains; but the possible importance of the other ingredients should not be forgotten.

Tobacco-smoke, according to Ludwig's[13] analyses, contains ammonium carbonate, ammonium acetate, acetic acid, phenol (carbolic acid) and tar. Other observers have mentioned pyridin bases and empyreumatic oils. Which of these bodies is the irritant which induces leukoplakia and cancer, or whether several of them may not present the requisite irritating qualities, is beyond our ken. It is possible that phenol may be exonerated,[14] but further speculation does not appear to be warranted.

ANILIN DYE CANCER

Formerly it was supposed that workers in anilin dyes were free from lesions induced by their occupation;[15] but the demonstration that deaths from bladder tumors are thirty-three times as frequent among dye workers as among the population in general,[16] and the experimental production of epithelioma-like tumors in man[17] and in animals[18] by means of a great variety of anilin derivatives and products of tissue decomposition,[19] has thrown the actual relation into bold relief. The substances possessing the necessary irritative qualities resemble each other in that they are hydroxylated aromatic amido-bodies. Most of them are distinctly coal and petroleum products and, therefore, the chronic-irritation tumors which they induce belong in the tar and paraffin cancer group.

CHIMNEY-SWEEP'S CANCER

Chimney-sweep's cancer is undoubtedly due to the irritation of soot and has been regarded as a clinical entity since its description by Percival Pott[20] in 1775. It is a typical epithelioma, occurring as a rule on the scrotum — although arms, hands and thighs may be attacked — and running a very chronic course leading to ulceration, metastases and death if not interfered with. The disease is rarely seen except in England and seems to be associated etiologically with the kind of coal which is there used for fuel. Curling[21] says that pit-coal, from which soot is produced, is very sparingly employed as fuel elsewhere than in England, and Baum[22] has shown that chimney-sweep's cancer was unknown in Hanover until wood was supplemented by coal for fuel.

During the years 1900, 1901 and 1902, the comparative mortality-figure[8] for cancer among English chimney-sweeps from the ages of 26 to that of 65 was 133 as compared with 63 among occupied males at the same ages. Apparently, soot produces irritation of the skin similar to that produced by paraffin and tar, and with similar results.

KANGRI-BURN CANCER

In 1910 E. F. Neve[23] reported on the occurrence of the so-called kangri-burn cancer. Of 4,902 tumors removed by operation in the Kashmir Mission Hospital in the course of twenty-five years, Neve found that 1,720 were malignant; of these 1,189 were epitheliomatous and 484 were on the thighs or abdomen and were due apparently to the irritation of the kangri, a portable fire-basket carried by the people under their clothes.

Kangri-burn cancer is a typical squamous-celled epithelioma. In the early stages the malignancy is slight, the glands are slow to become infected and the disease is readily amenable to operation. It is demonstrably due, according to Neve, to a definite cause, namely, irritation from the constant application of heat. The preepitheliomatous skin changes resemble closely those seen in paraffin- and tar-workers. It is extremely common to find dry, scaly, pigmented spots or patches slightly raised from the surface. The skin is often mottled and pigmented, and shows the lines of distribution of superficial veins. Horny tumors are not rare, and sometimes at their base transition into epithelioma can be demonstrated. There is also a condition allied to chronic eczema in which there is redness and a tendency to desquamation. This gradually shades off into the actual formation of scar-tissue. Objection may justly be raised to Neve's dogmatic assertion that such changes are due to irritation by heat, for the skin of these patients is subjected to other causes of irritation in the soot and gaseous emanations from the fire-baskets.

SUMMARY

The similarity of the lesions following the types of chronic irritation which have been briefly described suggests the probable similarity or possible identity of the irritating agents or agent concerned. Is this factor merely the mechanical effect of the presence of minute foreign bodies — soot — on and in the skin? Probably not; and the best argument against the idea seems to be furnished by the fact that workers in blast-furnace tar escape cutaneous involvement while workers in gas-works tar usually suffer from skin lesions, and the exposure to tar or pitch-dust is the same in both cases. Can the lesions be the result of prolonged exposure to heat and repeated burns? Probably not, because this would never account for the bladder tumors of anilin-workers, and most of the labors of paraffin- and tar-workers and chimney-sweeps are carried on at room temperature or outdoors, and these men are not the victims of frequent burns. This brings us to the assumption that there is some chemical body (or bodies) resident in certain coal and petroleum products which are capable of inducing inflammatory productive reactions in tissues and eventually atypical, unrestrained proliferation of epithelial cells. In favor of this suggestion let me cite several facts.

Physicians of large experience in paraffin prosthesis demand paraffin of the very highest purity for their work, because it seems that paraffinomas, that is, inflammatory tumors which occasionally develop at the site of a paraffin injection, are especially apt to appear following the use of paraffin of inferior grade.

Epithelioma develops earlier and with greater malignancy in workers in fluid tar and paraffin than in those who are subjected merely to the dry dust and soot. This observation agrees with the generalization that substances are most active chemically when in solution.

None other than a chemical cause seems possible in relation to the bladder tumors of anilin workers, and to the betel-nut and tobacco cancers.

Ross, Cropper and Ross[5] assert that they have demonstrated the existence of a number of chemical bodies, twenty-five or thirty, which are capable of inducing cell division *in vitro;* these bodies they term "auxetics." Auxetics have been demonstrated in gas-works tar but not in blast-furnace tar; moreover, Bayon[24] was able to induce atypical epithelial overgrowths in animals by the use of gas-works tar containing auxetics, while experiments with the auxetic-free blast-furnace tar resulted negatively. Ross, Cropper and Ross place certain products of tissue decomposition among the auxetics and suggest that the latter may be responsible for the proliferation of tissue which occurs in healing wounds, and that their continued presence in tissues for a long period, as in areas subjected to "chronic irritation," may be the factors which determine malignant degeneration in such areas.

Schamberg suspected radio-activity as the possible exciting force in tar products, but its presence could not be demonstrated in specimens examined for him at the University of Pennsylvania.

CONCLUSION

It would seem fair to assume that the chronic-irritation cancer produced by coal and petroleum products is a chemical-irritation cancer, and that it is not impossible that the cancer following chronic irritation of other origin may be of an essentially similar nature.

I am greatly indebted to Dr. Arthur Dean Bevan for permission to report this case and for assistance in gathering data on it.

Mental Diseases.—We talk a great deal about the human mind, and, when cornered, quote Hamlet to cover an unpleasant ignorance of its true nature. The modern student, like the ancient, takes his stand either with Plato and compares the mind and brain to a player with his musical instrument, or with Lucretius to a musical box wound up for so many years to play so many tunes. Authorities lean to one or other of these views, and I have a shrewd suspicion that some of our distinguished visitors, great representatives in this specialty, do not see eye to eye in this matter. Three things we do know, departures from normal states are extraordinarily common—they are the most distressing of all human ills—they should be studied systematically by experts, with a view to their prevention and cure.—Osler: Specialism in the General Hospital.

ELEPHANTIASIS AND THE KONDOLEON OPERATION *

HUBERT A. ROYSTER, A.B., M.D.
Surgeon to Rex Hospital; Surgeon-in-Chief to St. Agnes Hospital
RALEIGH, N. C.

In my section of the country, elephantiasis is certainly an uncommon disease. My only case, and the only one so far recorded by any observer from this state, is the one herewith presented. By a fortunate circumstance, about the time this patient was admitted, there came from Dr. Rudolph Matas[1] of New Orleans his monograph on elephantiasis, which sums up all that is known of this disease and its kindred affections up to the present time, and to which I am indebted for valuable information. Particularly do I wish to testify to the benefit derived from an operation proposed by the Greek surgeon Kondoleon, to whom Matas gives full credit.

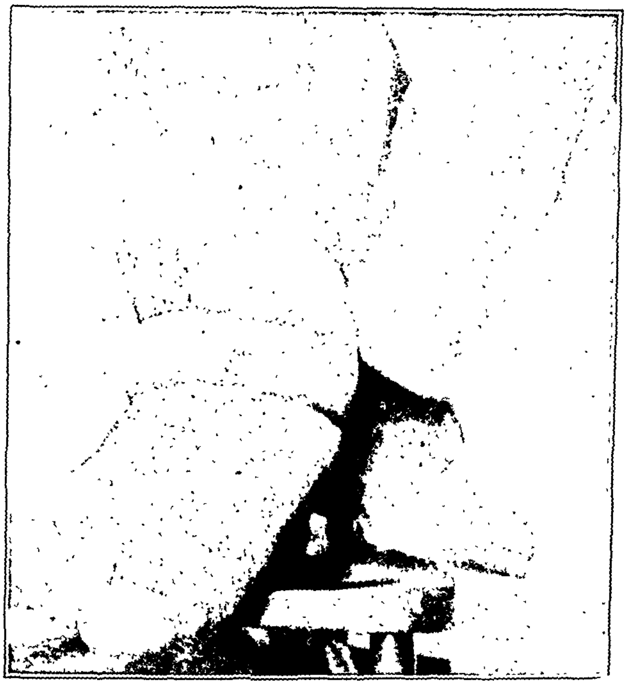

Fig. 1.—Elephantiasis of leg, front view.

History.—Charles P., a mulatto, aged 23, was referred to me in December, 1913, by a physician in Sanford, N. C., with the suggestion that I should amputate his leg. The patient was willing to submit to amputation, since he was no longer able to do his work as a cook. Born in Virginia, he went to Philadelphia at the age of 16, and after twelve months shipped to Florida. For two and a half years he remained in that state, living at different times in Jacksonville, Tampa and Key West. Later he moved to South Carolina, and that is his present home. During the summer of 1911 his right leg and foot began to swell, following an acute attack, accompanied by pain, redness and fever. In the winter months the condition improved, but each summer the swelling, pain and fever returned. The leg has steadily increased in size until it seriously interferes with his occupation. Locomotion is difficult and wearing of ordinary trousers impossible.

* Read by invitation before the Medical Association of the State of Alabama, April 23, 1914.

[1] Matas, Rudolph: The Surgical Treatment of Elephantiasis and Elephantoid States Dependent on Chronic Obstruction of the Lymphatic and Venous Channels, Am. Jour. Trop. Dis. and Prev. Med., 1913, i, No. 1.

Examination.—This disclosed a typical Barbados leg. The enlargement was confined to the right leg and foot and did not extend above the knee. The circumference at the calf was 22 inches, above the ankle 18 inches and of the foot 14 inches. The skin was exceedingly hard, thick and rough; in some portions it was scaly, in others horny; at the bend of the ankle there was a wide fold, which prevented proper motion of the joint. There could be no difficulty in making a diagnosis of elephantiasis (Fig. 1).

Detailed investigation elicited the following: The Wassermann reaction was negative; repeated study of the blood, taken at various hours of night and day, and continued over several weeks, showed no filariae; at one time a decided eosinophilia (11.2 per cent.) was present; the urine was normal. The eosinophilia was most probably due to an accompanying hookworm infection, as the eggs were found in the feces.

Operation and Result.—In the management of the case the patient was first assured that the sacrifice of his limb must be the last resort. After going over carefully all the procedures proposed for the relief of elephantiasis, it was decided to do the Kondoleon operation. For four days previous the man was put to bed; each day the leg and foot were scrubbed in a strong mercuric chlorid solution, bandaged tightly with a Canton-flannel roller and kept elevated on pillows. As a result of this, the leg was reduced in size about 2 inches. Jan. 3, 1914, the operation was performed as follows: A long incision was made through the skin on each side of the leg, extending from knee to ankle. Wide retraction of the integument was secured by dissecting it back freely from each edge of the incision. Going from above downward, the deep fascia to the width of three fingers was dissected off the muscles and cut away in one piece of the length of the wound. Also, the same area of subcutaneous tissue was removed by splitting it off the skin. The muscles were laid bare and free hemorrhage occurred, requiring many ligatures. The skin was stitched back in position, dressings applied and the leg bandaged without a splint.

One week later the first dressing revealed primary union, except at the lower third of the incision on the outer side of the leg, where sloughing of the skin edges had occurred. Undoubtedly too much of the subcutaneous tissue had been removed, leaving the skin at that point thin and poorly nourished. The whole leg was very much smaller (17 inches at the calf) and the ridge across the ankle had disappeared (Fig. 2). One month afterward further progress was evident: the leg had diminished in size, the foot was much more flat and the patient could walk with comparative ease. Feb. 12, 1914, he was exhibited to the Wake County Medical Society. At the present time (April 23, 1914) the improvement is still evident; there has been no going back. The patient is able to get about and will probably take up his work in a short while.

The auxiliary treatment consisted, first, in the hypodermic administration of thiosinamin (fibrolysin) every three days, over a period of two weeks while the patient was in bed. On two occasions a marked reaction resulted from an ordinary dose and it had to be given in smaller quantities. Then, on April 10, an intravenous injection of salvarsan was given empirically, for the purpose of combating the possible parasitic or microbic origin of the disease, in spite of our inability to demonstrate the presence of any infective organism. Since the injection the eosinophils have reduced to 6 per cent. It is too early to predict the final result.

Comments on this case will naturally include some account of recent advances in the study of the etiology and pathology of elephantiasis. First and foremost it may be asserted that we have not yet arrived at the point of knowing the true nature of the disease. Of one important fact, however, we are quite sure — that not all cases are due to the *Filaria sanguinis hominis*, as was formerly taught. "It will be opportune to note the fact," says Matas,[1] "that the filarial or strictly tropical type of elephantiasis is practically unknown in Louisiana or on the Mexican Gulf Coast and in the South Atlantic States." And again, "The human filaria is very rare and, as a rule, imported from the West Indies and Central American countries. Even in these tropical latitudes, where elephantiasis is common (Barbados leg), its association with filariasis is not as frequent as one would suppose." It is barely possible that even with the utmost care one might fail to find the filariae, either because the exact time of their appearance in the circulating blood had not been determined, or because of a possible permanent clumping of the organisms in the lymphatics.

In the non-parasitic type of elephantiasis a number of causes are operative — traumatism, syphilis, phlebitis, skin-diseases, etc. Chief interest is now being given to the view that the majority, if not all, of this group of cases result from infection with a streptococcus similar to or identical with that of erysipelas, and that the clinical histories will bear this out. Even in the parasitic varieties Manson, the discoverer of the filarial origin of the disease, has been quoted as saying that "a secondary microbial infection of the obstructed area is necessary to cause the tissue changes of elephantiasis." The story of my case seems to give credence to the erysipelas theory and will serve to keep before us the suggestion of Matas to administer "a systematic course of treatment with polyvalent antistreptococcic serum to be injected in doses of 10 c.c. at least three times weeky." For the present, I shall wait for whatever effect the salvarsan may have and then decide on what further course to pursue.

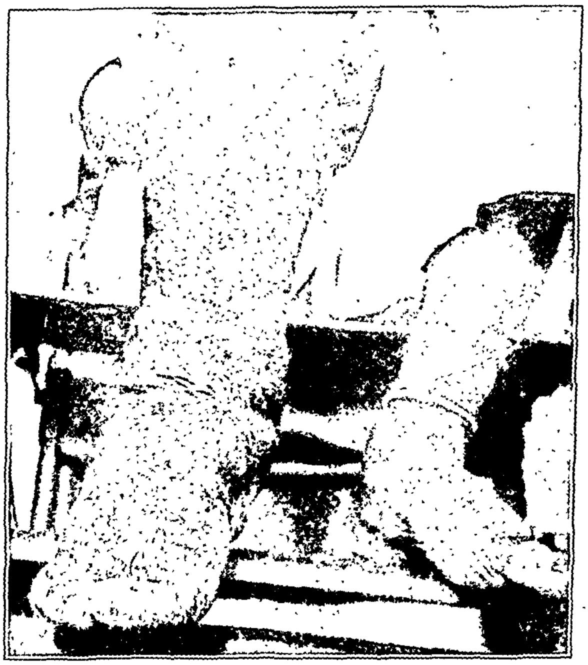

Fig. 2.—One week after operation.

It will not be necessary or expedient to rehearse the many procedures which have been employed from time to time in the alleviation of elephantiasis. Suffice it to say that no method or combination of methods has yet proved to be absolutely curative. Kondoleon's plan, with which we are here concerned, was evolved from the idea of Lanz of Amsterdam, who referred to his procedure as a "deep lymphatic derivation." But Lanz's operation is technically difficult, while the method offered by Kondoleon is simple. The principle involved is that, by removal of the deep fascia, there is brought about an anastomosis between the deep and the superficial lymph-spaces. The operation is new and has not been performed in a sufficient number of cases to warrant any definite opinion; Kondoleon himself has done it but six times, and, though his reports were favorable, only two months had elapsed since the last operation. I can say, however, that the method appeals to me as rational and that, so far, the result in this one case is satisfactory.

At this writing, more than three months after the operation, the measurements of the affected leg are: calf 15¼ inches, above the ankle 15½ inches and foot 13¼ inches. The sound leg shows the following: calf 15½ inches, above ankle 10½ inches and foot 10½ inches. It will be noticed that very little decrease has been secured in the size of the elephantiac foot, and I would propose a similar operation in that region as the next step, provided it could be done without damage to the tendons. The skin over the whole leg is much smoother and quite movable over the underlying tissues.

TRAUMATIC DETACHMENT OF THE BLADDER FROM SYMPHYSIS PUBIS WITH COMPLETE SEVERANCE OF URETHRA

USE OF THE LABIA MINORA AS A SUBSTITUTE FOR NECROSED ANTERIOR VAGINAL WALL

AXEL WERELIUS, M.D.
CHICAGO

Pressure necrosis of the anterior vaginal wall, due to prolonged and difficult instrumental labor, is not a very frequent complication, especially to the extent in which it occurred in the case reported below, in which the urethra had completely disappeared and the bladder was entirely detached from the symphysis, suspended only by the ureters and the peritoneum covering its posterior surface.

The literature on the subject of the traumatic separation of the bladder from the symphysis is somewhat meager, and this case seems to be the first reported as occurring from labor.

Ludolf Süssenguth[1] reports a case observed about the same time as mine. He states that he found only three other cases in the literature, those of Bartels, Grossich and Stierlin.

These cases were all produced by a sudden trauma. Whether the condition in my case was brought about by sloughing, following a prolonged and excessive pressure on the parts involved, or suddenly produced by the organ being torn loose during a difficult instrumental delivery, I am unable to determine, as I saw the case at first five months after the confinement, and in the interval the patient had never been examined. The severance of the urethra, however, took place at once, as incontinence of urine followed immediately after the labor.

Stierlin[2] endeavors to explain the mechanism of the injury to his patient, a young man who had the pelvis compressed between two wagons, by contending that there was a momentary dislocation of the symphysis, the two pubic rami overriding each other, thus tearing the bladder loose.

In Süssenguth's case the most careful post-mortem exploration failed to reveal any injury to the symphysis or any of the surrounding bony structures. He reasons that the partly filled bladder extending somewhat above the pubis was forcibly pushed backward; its connections to the symphysis, being unequal to the strain, gave way, at the same time tearing the urethra.

Stolper,[3] fortified by extensive researches on injuries in this region, believes that outside of a diastasis, isolated luxation of the symphysis could hardly occur. This somewhat antagonizes the theory of Stierlin, favoring the simpler explanation of Süssenguth.

Aside from the unusual pathology, my case might be of some interest from the mode of vaginal repair. After having twice vainly endeavored to close the gap left by the necrosed anterior vaginal wall, by using the remnants of this wall and nearby structures, I used the labia minora as a substitute for the absent vaginal tissue.

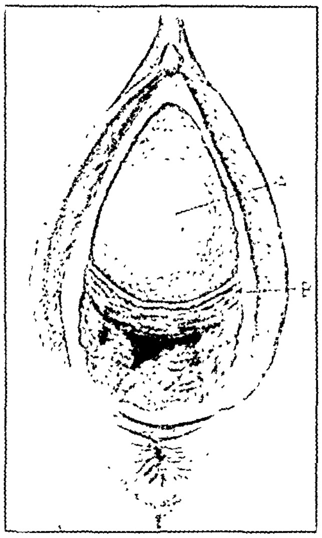

Fig. 1.—*A*, dislocated bladder; *B*, edge of necrosed vagina.

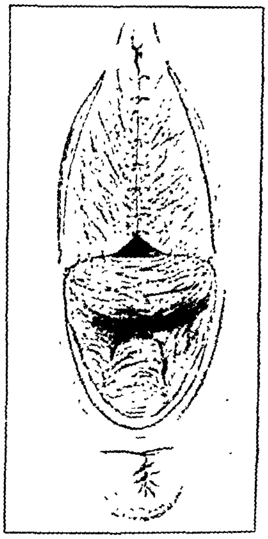

Fig. 2.—Labia minora as substitute for necrosed anterior vaginal wall (semidiagrammatic).

REPORT OF CASE

History.—The patient, a woman aged 32, was admitted to South Shore Hospital, March 5, 1913. Following a very tedious and difficult labor terminated instrumentally Oct. 7, 1912, the patient has been unable to hold her urine. For weeks subsequent to the confinement there was a foul vaginal discharge, followed later by a profuse leukorrhea, lately, at times mixed with blood. The patient also complains of pains in the pelvis, radiating down the limbs and into the back, aggravated by exertion. The appetite has lately been very poor. The bowels are greatly constipated. She is becoming more and more nervous and irritable and has lost in weight and feels very weak. The past history and family history are negative. The patient's habits are good. Menstruation is greatly lessened but regular.

Examination.—The general appearance is that of a poorly nourished young woman. Head, neck, chest and extremities are negative. The lower abdomen is somewhat tender on palpation. Vaginal examination reveals an almost complete absence of the anterior vaginal wall. On increased abdominal pressure the bladder protrudes far out of the vagina (Fig. 1); the bladder wall seems highly congested and bleeds easily. There are no signs of any urethra. The bladder seems to be suspended only from the ureters and its posterior peritoneal covering. The under surface of the symphysis is palpable. Blood examination reveals: erythrocytes 3,400,000; leukocytes 8,200; hemoglobin 65 per cent. The urine contains a large amount of albumin, but no casts.

---

[1] Süssenguth, Ludolf: Deutsch. Ztschr. f. Chir., cxix, 490.

[2] Stierlin: Beitr. z. klin. Chir., lxv, 616.

[3] Stolper: Deutsch. Ztschr. f. Chir., lxxvii, 498.

Operation and Result.—Three attempts were made to close the defect. The first operation was done March 10. The edges of the remains of the vaginal wall were freshened and undercut, and brought together anteroposteriorly with chromicized catgut and an opening left for the escape of the urine. Two weeks later the condition was about the same as before operation. April 14 I operated again. The edges were freshened and undermined as before but united laterally with strong silk. These silk threads formed nuclei for calcareous deposits which in a few weeks almost cemented the entire vagina, causing considerable pain and discomfort. The last operation was performed May 5. The bladder was found to be held up fairly well from perivesical adhesions. The edges of the labia minora were freshened and incised along the outer and upper borders and dislocated inward over the vaginal defect and sutured with chromicized catgut as in Figure 2.

On reexamination, September 12, the patient had gained over 20 pounds. The pain had disappeared. The flaps partly held. Feb. 2, 1914, the local findings were about the same. There was no pain. The general condition was good.

1230 East Sixty-Third Street.

A CASE OF ACUTE NICOTIN POISONING OF PECULIAR ORIGIN

Harry S. Reynolds, M.D., New Haven, Conn.

The following case seems worthy of brief mention not only because of the rarity of occurrence of severe acute nicotin poisoning, but particularly owing to the peculiar circumstances of its origin.

At about 10:30 a. m., April 14, 1914, Rudolph D., a well-nourished infant aged 5 months, was brought into my office *in extremis* by its mother, a Slav woman, who stated that the baby had swallowed some tobacco.

On careful questioning I elicited the following history from the mother: The patient was a bottle-fed infant, and on the preceding night, according to her usual custom, the mother had prepared a mixture of milk and water which she left in a basin on either a stove or a table in the kitchen. The patient, who had apparently been in excellent health, was fed some of this mixture at 1 a. m. and again at 4 a. m. At 5 a. m. the mother discovered some tobacco in the bottle nipple, and on investigation found some more tobacco (quantity indefinite) in the milk basin, on which she threw out this milk mixture and made up a new one, which was fed to the baby at 6 a. m. Shortly afterward she went out to work, leaving the infant in the care of his father. A little later the patient began to show signs of distress and vomited twice. The mother was summoned and later sought medical aid as above stated. On the preceding evening the father had entertained some friends at his home and apparently, as all hands were smoking, some one in the party had carelessly spilled or discarded the tobacco which was found in the basin.

The patient, when first seen by me, was cyanotic and in a state of collapse. His head was sweating profusely and his extremities were cold and clammy to the touch. There was some twitching of the muscles of the face. Both pupils were widely dilated. The pulse was weak and irregular, the circulation having a pronounced tendency to fail, but responded temporarily to stimulation. Respiration was slow and labored and marked by a loud inspiratory gasp; breathing at times became so slow that artificial respiration was resorted to on several occasions.

Atropin, strychnin, brandy, epinephrin, coffee enemas, external heat and gastric lavage were administered and early in the afternoon he was apparently much improved, but at 3:30 p. m., at a time when his condition seemed quite favorable, respirations suddenly ceased entirely and on immediate investigation the heart was found to have ceased beating.

The post-mortem appearance was remarkable, the skin becoming almost immediately covered with purple blotches, which varied from the size of a ten-cent piece to that of a half dollar—an appearance which was interpreted as indicating the results of a condition of extreme vasomotor disturbance.

As the father's company left the house at midnight, the inference would seem to be that the tobacco found its way into the milk and water mixture before the 1 o'clock feeding, nicotin having then begun to extract out, and that at the 4 o'clock feeding the infant received the maximum dose of nicotin extract.

321 Grand Avenue.

DEAF-MUTISM (LABYRINTHINE DEAFNESS) AS A RESULT OF PURPURA HEMORRHAGICA*

G. W. Stimson, M.D., Pittsburgh

J. D., girl, aged 4, white, American, was referred to me, Jan. 7, 1914, by Dr. R. H. Boggs of this city, the patient coming from Maryland. The complaint was deaf-mutism. The family history of the little girl was good. She was accompanied to my office by her father and mother, both of whom were healthy. The patient had been a perfectly healthy child, normal in every respect, until she reached the age of 23 months. She heard sounds readily, started at noises and responded as intelligently as any child of her age to questions and speech directed to her by her parents. She had acquired quite a vocabulary so that her speech was well advanced for a child of her age. She could repeat anything she was told. There was never the slightest question of her intelligence or her ability to hear as well as any one.

When she was 23 months old she was seized with an attack of purpura hemorrhagica. Her parents state that within a day or two after the onset "she went stone deaf and has remained so ever since."

She is a bright, intelligent-looking little girl, apparently normal in every way except as indicated.

Examination of the nose and throat showed nothing abnormal. The external ears, auditory canals and tympanic membranes were normal in every respect. As the child seemed frightened and was examined with considerable difficulty, no tests were made of the irritability of the labyrinths to stimuli, as demonstrated by use of the caloric test, the turning test or galvanism.

The child's deafness is absolute. Her attention is not attracted by any sounds or noise however loud. Tuning-forks placed on vertex and mastoid processes produced no perceptible change of expression. She has progressively lost her power of speech until now she retains only one or two words, chiefly an almost unintelligible "ma-ma."

The diagnosis seems to be obviously that of labyrinthine deafness due to severe hemorrhage into both labyrinths at the time of the attack of purpura hemorrhagica. The hemorrhage was probably of such extent that complete disorganization of the parts took place from pressure, and a return to the normal condition became impossible even though the effused blood was subsequently absorbed.

As practically all children who acquire deafness under 7 years of age, and invariably a child as young as this one, promptly forget the few words they have learned, the loss of the sense of hearing inevitably leads to the development of mutism as well, as it has done in this case.

In none of the text-books on diseases of the ear at hand is any reference made to purpura hemorrhagica as an etiologic factor in the production of acquired deaf-mutism or labyrinthine deafness.

A SATISFACTORY LOCAL ANESTHESIA FOR THE SUBMUCOUS RESECTION OF NASAL SEPTUM

James Joseph King, A.B., M.D., New York
Attending Laryngologist to the Hospital for Ruptured and Crippled

Realizing the difficulties encountered by many in securing a satisfactory local anesthesia for the submucous resection of the nasal septum, I offer to the profession this method, which has been very satisfactory to me in over four hundred resections. Some years ago I was not entirely satisfied with any of the methods I had seen used and I began to try out various methods in the hope of securing a technic that would eliminate the objectionable features of all methods, which are fright, nervousness, toxicity from cocain and epinephrin solution, shock, hemorrhage obscuring the operative field and the sequelae of severe headaches and toothache as the effect of the cocain wears off.

The several elements in my anesthesia are not original, but as far as I am aware the whole technic is original and is given below.

Half an hour before I begin to produce the local anesthesia the patient receives by mouth 1/150 grain scopolamin hydromid. This drug allays the patient's fears, overcomes any nervousness and is the therapeutic antagonist to cocain. It is used extensively by neurologists in the treatment of the insane and very nervous patients.

Half an hour after the patient has taken the scopolamin, I apply with a cotton wound applicator to every portion of the mucous membrane of the septum a 20 per cent. solution of cocain hydrochlorid, first painting very gently over every portion of the septum on the right side and then on the left side. Immediately after the first application over both sides of the septum I repeat the application as before. This makes two complete applications of a 20 per cent. solution of cocain to each of the septal mucous membranes. For each application I use a fresh cotton wound applicator moistened with the 20 per cent. cocain solution.

These two applications of 20 per cent. cocain solution are followed immediately by a similar application to every portion of the septal mucous membrane of a solution of 1:1,000 epinephrin solution. I then inject under the septal perichondrium and periosteum on each side from 8 to 10 c.c. of a sterile normal salt solution to which 5 minims of 1:1,000 epinephrin solution has been added immediately before injection. This injection completes the anesthesia, infiltrates every portion of the septal membrane, blocks off the nerves preventing shock and renders the operation practically bloodless. It also aids very materially in elevating the perichondrium from the cartilage so that the dissection of the mucous membrane and perichondrium is quite easy.

I use only 5 minims of epinephrin solution in the injection because this amount does not exceed the physiologic dose by hypodermatic injection, and experience has proved to me that this amount will render the field bloodless without producing toxic symptoms.

40 East Forty-First Street.

The Cost of Pasteurizing Milk.—In Bulletin 85 of the Department of Agriculture it is estimated that the cost of pasteurizing with a properly operated plant averages for milk 0.00313 cents a gallon and for cream 0.00634 cents. Tests also show that the "flash" process, by which milk is raised to 165 F. and kept there for a moment only is more expensive than the "holder" process, by which milk is held at the temperature of from 135 to 145 F. for thirty minutes. The "holder" process has been found to require 17 per cent. less heat than the "flash" method, and there is also a saving in the expense of cooling. For hygienic reasons also, the "holder" process is to be recommended. An item of economy in the pasteurization of milk is the utilization of exhaust steam from engines and steam-driven auxiliaries. An arrangement by which the pasteurized milk is made to assist in heating up the raw milk may aid the economy of the process.

Therapeutics

SOME OVERLOOKED CAUSES OF CHRONIC ILLNESS

(*Continued from page 1638*)

CHRONIC DYSPEPSIA

Before a condition is termed dyspepsia, nervous dyspepsia, chronic gastritis, or intestinal indigestion, although any one of these conditions may be present, we should most carefully seek the cause. This large subject is referred to only to present some of the frequently overlooked causes of chronic indigestion; we should never be satisfied with any one of these diagnoses.

Frequent causes of these digestive disturbances are reflexes from eye-strain, or from the appendix, ulcer of the stomach or duodenum, reflexes from the gallbladder and a loose kidney. The frequency of these etiologic factors perhaps is in the order named. Ptosis of the abdominal organs is more or less readily determined, and need not be here considered. Also, it is not necessary to refer to the classic symptoms of any of the above-mentioned causes of indigestion, but it is urged that clinicians should never be satisfied to say that the condition is one of gastric hyperacidity, or that there is insufficiency of hydrochloric acid in the stomach, or that a patient has recurrent "bilious" attacks.

Chronic appendicitis, or, perhaps as frequently, pericolitis with adhesions around the colon in the region of the appendix, generally caused by a previous appendicitis, can give reflex pain referred to the cap of the duodenum, and can cause hyperacidity and dyspepsia, which may sooner or later cause epigastric tenderness and symptoms of disturbance in the upper abdomen. A chronic irritation of the appendix may cause only gastric flatulence. Sometimes the region of the appendix will be found entirely insensitive, but we should make repeated abdominal examinations of a patient who has indigestion and is not benefited by the ordinary corrections of diet and simple medicinal treatment. Also, we should urge that whenever the patient has an attack of pain he should be examined at once by his physician, and very often distinct, positive trouble will be found localized near the appendix.

On the other hand, prolonged irritation in the abdomen may allow ulcer of the stomach or duodenum to develop through the irritation of the mucous membrane of the stomach and destruction of the protective mucus, which results from the protracted hyperacidity. It seems to be a fact that hyperacidity of the stomach is a preliminary stage of gastric ulcer, and likewise of ulcer of the upper part of the duodenum. One factor in the cause of ulcer of the stomach seems to be the absence of normal mucus protection, and anything which will cause the mucus coating of the stomach to become normal tends to prevent erosion. We can readily understand this when we note the irritation that occurs in a dry throat, larynx or trachea; anything that tends to increase the mucus in these regions cures the condition. We should, therefore, recognize a preulceration stage of gastric or duodenal ulcer, in which there is likely to be hyperacidity; the cause may be great debility, mistakes in eating, or a chronic appendicitis. The immediate treatment of such a condition by proper diet and improving the general condition of the patient, with the removal of an irritating factor, if such be found, may prevent ulcer.

A few suggestive points of diagnosis may not be out of place. In chronic appendicitis or pericolitis there is generally (but not always) tenderness, if not pain, referred to the appendix region, also flatulence, gastric and intestinal, and constipation. There is rarely much tenderness in the epigastric region, certainly not acute. The appetite is generally poor, the tongue coated. Taking food and liquids into the stomach does not ameliorate and may increase the discomfort, which is usually not true of ulcer of the stomach. The position of the body does not change the character of the pain, distress and irritation.

Some of the symptoms of ulcer of the stomach generally present are: pain, often relieved or aggravated by a change in position, usually relieved by eating, unless the food is irritant; irregular appetite; tenderness on palpation; constipation, hyperacidity, and red tongue, unless there is gastric retention. Vomiting and bleeding are not constant, and both may be absent. If frequent projectile vomiting is present, or blood is vomited or frequently appears in the stools, of course the diagnosis becomes more positive. Pain from ulcer of the stomach is readily soothed by bland food, and especially by milk of magnesia. This is not true of referred appendix pain or of ulcer of the duodenum, although milk of magnesia (magna magnesiae, N. F.) may stop the pain promptly in the latter condition.

In ulcer of the duodenum the pain is likely to occur three hours or more after eating, and often awakes the patient in the night. The appetite is generally good; the tongue somewhat coated; the tenderness is rather distinctly localized; the bowels are irregular, sometimes loose, sometimes constipated, and the pain is more intermittent and not so constant as in ulcer of the stomach.

It is not necessary to refer to the classic signs of gall-stones or gall-bladder disturbances. The importance of examining the stomach contents, also the feces for occult blood, and taking roentgenograms after a bismuth meal need not be emphasized, but sometimes all kinds of examinations will still leave the diagnosis uncertain until the abdomen is opened.

It has lately been urged that in the diagnosis of gastro-intestinal disturbances we have not given sufficient importance to the determination of indican in the urine. It is asserted that all anatomic lesions of the gastro-intestinal tract will show continued indicanuria. On the other hand, a functional indicanuria may be prevented by free catharsis and regulation of the diet, and especially by several washings of the colon. If indican is repeatedly present after good catharsis and several days of a simple diet, some lesion in the abdomen should be strongly suspected.

FLOATING KIDNEY

The symptoms caused by a loose kidney vary from none to those of serious indigestion, and those produced by pressure in different parts of the abdomen or caused by the kidney dragging on its ligaments. A properly fitting abdominal bandage, with or without a kidney pad, may entirely remove all signs of trouble, and such a bandage may really be a properly made corset, as the majority of loose kidneys occur in women.

As the right kidney is most frequently the one that is loose, the symptoms sometimes simulate gall-bladder disturbance or appendicitis, and a wrong diagnosis of the condition is often made.

Because a patient has a loose kidney, operative procedures to replace it are not necessarily indicated. On the other hand, such an operation not infrequently becomes the only means of curing the reflexes caused by such a kidney or the colics and dangers resulting from the twisting of the kidney on its pedicle.

This condition is referred to because such a kidney is so elusive and a diagnosis of this cause of the abdominal disturbance is often very difficult to make. An abdomen may be repeatedly examined and a loose kidney not discovered, while at a subsequent examination a kidney that can be depressed to the brim of the pelvis may be found.

The amount of gas in the intestine at various times may determine whether the kidney will stay in place or whether it will drop to the length that its loose ligaments allow. It is a fact, however, that without making an examination when the patient is standing, another when the patient is lying down and another after the patient has taken some rapid, deep breaths or has done some jumping (and even then there must at times be repeated examinations), it cannot positively be determined that a kidney is not loose and is not a cause of the abdominal symptoms.

PLEURISY

Pleurisy with effusion is perhaps often overlooked. Those who examine patients for entrance to tuberculosis sanatoriums understand this fact more fully than those who are not called on to note the previous history of many cases of pulmonary tuberculosis. The inflammation may be so insidious that a physician is not called before the effusion is present. The effusion may not be large, and the transmission of the voice and respiratory sounds may be so distinct that the condition is supposed to be that of a consolidated lung. Or, if on the right side, and the effusion is small, the liver may be thought to be enlarged. On the left side the condition may be taken to be an enlarged spleen. The mistaken diagnosis is serious, because pleurisy with effusion is so generally tuberculous in origin, and if adhesions are formed when the fluid remains in the pleural cavity the lung will never again expand to its proper size, and tuberculosis of the lungs readily begins. It is suggested in such cases that a long hypodermic or exploratory needle, or an aspirating needle be inserted. The simplest kind of aseptic technic will preclude any harm; and many times, in doubtful cases, we cannot make a diagnosis of the condition without such a practical test.

CERVICAL OR FALSE RIB

Some recurrent neck, shoulder and arm neuralgias, which are benefited only to recur again, may be due to this condition. Careful examination of the neck and roentgenograms may show that such a rib is pressing on a nerve trunk. Such a bone growth may also cause either disturbance in the subclavian artery, or muscle pains or contractions in the neck. Such possible causes of disturbances in the neck and shoulder region should not be forgotten. They are said to be more frequent in women than in men, and when present are bilateral in about 70 per cent. of the cases. The growth generally occurs from the transverse process of the sixth or seventh cervical vertebra.

SOME NEWER ASPECTS OF ACIDOSIS

The modern physicochemical study of the blood has clearly shown that the reaction of this fluid undergoes comparatively little, if any, change even under conditions approaching extreme acidosis. From this point of view the blood and tissue fluids maintain an unvarying alkaline reaction or neutrality. These terms may be used interchangeably for an alkalinity which is actually so slight.

The foregoing statements, which are everywhere accepted in scientific circles, have been the occasion for not a little confusion in the minds of those who were trained in the older school of chemistry and have not fully succeeded in grasping the importance of modern physicochemical conceptions. The physical chemist measures the reaction of a fluid by the balance between the hydrogen and hydroxyl ions which it contains. Examined by this standard, the blood has an extremely low concentration of hydroxyl ions; indeed, it is scarcely more alkaline than distilled water. It is this low hydroxyl ion concentration which varies so slightly even under extreme pathologic conditions. On the other hand, there is an excess of replaceable bases over acids in the blood; and the reaction of this fluid was formerly expressed in terms of its behavior toward indicators and its ability to neutralize acids. In this sense the blood is definitely alkaline toward the majority of indicators, and it has therefore commonly been spoken of as an alkaline fluid. This behavior of the blood with indicators toward acids and bases has been termed its "titratable alkalinity," in contrast with its hydrogen ion concentration, or reaction in the physicochemical sense.

With the advent of the newer ideas and the demonstration of admirable regulatory functions by which the physicochemical reaction of the blood was maintained unchanged despite great variations in the contribution or abstraction of acid and basic radicals, doubt began to be expressed regarding the validity of the older ideas and procedures. It was suggested that the "titration" of the blood must be abandoned as a method of study, and that, primarily, in the urine is shown the result of the prompt adjustment occurring in acidosis. For, obviously, if in this excretion the proportion of acids and alkalies formed in metabolism or otherwise introduced is such as to maintain a constant neutrality in the organism, this excretion would seem to offer the best opportunity for the detection of changed relations.

Dr. Sellards[1] of the Johns Hopkins Hospital has come to the rescue of the older scheme of estimating titratable alkalinity in the blood and has shown the value which this procedure may have from a clinical point of view. The outcome of his studies shows that changes occur which give rise to distinct qualitative differences in the reaction of normal and pathologic serums to phenolphthalein. Conditions are readily obtained under which blood-serum, during an acidosis, is neutral or acid, whereas under the same conditions all normal serums are strongly alkaline. Definite changes in the titratable alkalinity occur in experimental and spontaneous acidosis, in certain nephropathies, and in some anemias. The method also affords information of value in the differentiation of certain obscure comas. Cases of diabetes occur in which the excretion of ammonia and of acetone and related bodies is normal, but the titratable alkalinity of the blood is decreased and the tolerance to bases is increased. This affords proof of a definite impoverishment in bases in these cases.

The titratable alkalinity is of important biologic significance, while the available evidence indicates that the physicochemical reaction of the blood is maintained at a fairly constant value, even in outspoken grades of acidosis. The parallelism between the diminution in titratable alkalinity and the increase in tolerance to fixed bases in diabetes and in the nephropathies affords crucial evidence that the increase in tolerance is practically due altogether to a deficit in the body alkalies or alkali-yielding substances.

THE GROWTH AND COLOR CHANGES OF HAIR

The attempt to find an illuminating account of the factors which may modify or determine the growth of hair will usually be a vain one. The older writers, who did not always hesitate to make dogmatic statements when they were required to produce a finished account, sometimes discussed the subject with considerable freedom. Not so the modern scientific author, who realizes that every sentence from his pen is likely to be subjected to the scrutiny and criticism of some one who has studied the topic at first hand. The general descriptions of the processes of growth have been satisfactory with respect to their histology. The hair follicle and its papilla, the proliferation of the cells on its surface, the development of keratin — all of the facts concerning these processes are permanent acquisitions of physiology, but they do not commonly rise to the level of practical problems. Why does or does not the hair grow in certain regions in certain individuals? What are the conditions contributory to growth? How are the natural changes in color brought about and what determines them? The physician is frequently asked such questions as these, and for a convincing answer to them he will search with little success.

---

[1] Sellards, A. W.: A Clinical Method for Studying Titratable Alkalinity of the Blood and Its Application to Acidosis, Johns Hopkins Hosp. Bull., 1914, xxv, 101.

Experimental studies in this field cannot readily be conducted on man. Certain facts are, of course, matters of common observation. The beard grows anew after shaving, and this tonsorial practice is believed to stimulate the growth of the hair. Precisely why it does, is not clear; though the stimulus which shaving applies to the skin is said to produce a reaction favorable to improved local circulation and nutrition of the areas involved. For the same reason, that is, increased cutaneous activity as shown by the sweat-glands and neighboring structures, the beard is said to grow more rapidly in summer.

Surgeons sometimes observe an unexpectedly intensive growth of the hairs in the immediate vicinity of suppurating wounds or in parts exposed to hot-air treatment. This may be interpreted as the outcome of the unusual hyperemia of the regions involved. Evidence of the probable accuracy of this view has been offered by the Greifswald surgeon, Georg Schöne,[1] in experiments with white mice. When pieces of the hair-covered skin were removed from the region of the back and again transplanted thereon, many of the hair follicles were noticed to atrophy at first; but presently an abnormally rapid and intense growth of hair ensued. This was especially conspicuous at the edges of the wounds. The active metabolism in the region of the healing and regenerating tissues is assumed to account for the result.

If the pigment which produces the natural color of the hair is lacking, the hairs present a gray or white appearance. The silvery color may further be due to the presence of more or less air in the hair. To account for the blanching of the hair — the familiar accompaniment of old age and a phenomenon which frequently begins long before middle life is fairly concluded—various views have been set forth at different times. The silvery gray appearance which is seen in aging persons is doubtless characterized to some extent by the occurrence of larger numbers of air cavities, and not by the destruction of the pigment as has frequently been postulated. For the hair pigment is among the most resistant of organic substances and can be destroyed only by the most vigorous chemical treatment. Destruction of the pigment—in distinction from the artificial coloring or staining of the pigment — is scarcely conceivable without decomposition of the hair itself. Dry hairs contain more air and therefore will appear somewhat lighter in color than moist ones; but black hair may be dried to the utmost without becoming white, and the hairs of mummies dried through the centuries still show their pigment precisely as do fresh hairs.

Some years ago Metchnikoff of the Pasteur Institute in Paris propounded a different theory of the mechanism by which black hair turns white.[2] According to him, the hairs are invaded at certain times by special phagocytic cells. These "chromophages" find their way to the pigment, which they engulf and carry with them in their exit from the hair. This view has, however, never been seriously accepted by those who have made first-hand studies of the subject.[3]

The true explanation of the familiar color-changes of the hair is probably to be found, not in a destruction of pigment already present, not in any bleaching of hairs already formed, but rather in a complete renewal of the hair. Pigmented hairs fall out and are replaced by unpigmented or white ones. The appearance of gray or white hair is therefore attributable to the formation of a new hair coat rather than by the alteration of the old one. Completed pigmented hairs never turn gray; they fall out. It is nevertheless observed that the process of pigment formation may cease during the development of a hair. In that event the tip will remain pigmented though the base appears white.

How are we to harmonize these statements, it may be asked, with the many published records of hair having turned white suddenly as the presumable consequence of fright or other profound emotion? A careful study of the reputed instances has invariably shown that they were mythical.[4] It is popularly related that Marie Antoinette grew gray during the night after she was condemned to be executed. It is true that at her death her hair was gray; but her biographers all record that her hair had been gray long before the time of her death. This may serve to illustrate the value of hearsay evidence and popular tradition.

The conspicuous changes which the color of the fur of certain species of animals undergoes at different seasons of the year, becoming white in the winter months, affords an opportunity of investigating this pronounced transformation seemingly so closely related to what is seen in advancing age in man. The studies of Schwalbe[5] have demonstrated that here too there is no alteration of the color of the summer fur. The dark hairs fall out as the season advances and white hairs grow in their place. No sudden mutations are found when accurate observations are instituted.

CARBON MONOXID AND CANARIES IN MINES

The usefulness of small animals in the detection of air vitiated by poisonous gases in mines has been well established. Their value has been attested not only in connection with possibilities of danger from this source in the ordinary processes of subterranean mining operations, but also in the rescue work which calls for the greatest of care and precaution to prevent harmful consequences to those engaged in it. Carbon monoxid, the most toxic of the mine gases, is always produced in mines in some quantity by the use of explosives in blasting. When large shots are fired, where the ventilation is poor, and the working-faces are too far ahead of the last break-through, harmful percentages of carbon monoxid and other poisonous gases may be encountered. Miners at some mines frequently go home sick from powder smoke. The latter has been reported to contain as high as 4 per cent. of carbon monoxid and the products of the explosion of guncotton are reputed to contain many times this proportion.[1] Carbon monoxid is the constituent of after-damp most insidious in its action, most difficult to detect, and responsible for most of the deaths caused by mine explosions. For these reasons it becomes highly desirable to have a practical and sensitive indicator of quantities of carbon monoxid which may be in even the slightest degree harmful to man.

The United States Bureau of Mines has of late undertaken an elaborate investigation to determine the relative usefulness or unsuitability of various readily available animals.[2] The problem here involved is not a new one. Small animals have been employed practically in connection with mine operations in England and presumably on the Continent also, for some time. The bureau has found canaries and mice to be suitable for the purposes here outlined, the birds being the more sensitive of the two species. They are, furthermore, easily obtainable and become pets of the men who have them. One of the new questions to be tested was whether canaries can be used repeatedly in exploration work without becoming less useful as indicators of carbon monoxid; that is, whether they become more or less susceptible to the poison after several or many exposures. Furthermore, it has been desirable to compare the relative behavior of men and small animals to carbon monoxid.

There is no complete agreement among the different investigators as to the comparative sensitiveness of canaries and men to the poisonous gas here under discussion. This need not entirely militate against the usefulness of the animals; for they undoubtedly give ample warning of percentages of carbon monoxid immediately dangerous to men. In defining the minimum harmful or poisonous concentration of the gas, Haldane states that 0.05 per cent. in pure air is just sufficient to produce in time very slight symptoms in man, and the same percentage produces very slight symptoms in mice. He states that 0.2 per cent. is very dangerous to man. According to the investigators of the Bureau of Mines, when the proportion of carbon monoxid is 0.15 per cent. canaries will show distress usually in from five to twelve minutes. With 0.2 per cent. of the gas it is apparent in from two to six minutes. With these percentages much longer time is required before distress appears in men, although in the case of some persons the effects, when they do appear, may last for hours. Men cannot stand the exposure to collapse from carbon monoxid as animals can. After distress and collapse canaries and mice recover quickly if given fresh air. In man, recovery is often a matter of days; and long-standing after-effects are by no means rare in the case of an intoxication like this which may deprive the hypersensitive nervous system of its proper oxygen supply for undue periods.

From the fact that certain individuals are able to withstand atmospheres that cause distress in other members of a group, it is sometimes concluded that some persons have an idiosyncrasy to the gas. This is always at best the explanation of last resource. It must be kept in mind that after-damp in different parts of a mine (in some places quite close together) will differ in composition to the extent—where the toxic dose is so small—that at one place an insignificant amount of carbon monoxid may be present while at another place, near by, a harmful proportion may exist. One person of a party unknowingly may encounter the latter atmosphere while his comrades do not. The quantity of the poisonous gas absorbed depends, furthermore, on the air breathed. Moderate exertion may increase the volume intake per minute to several times the normal at rest. It follows, therefore, that if certain members of an exploring party work harder than others they will become poisoned more quickly than the less active members.

It is also occasionally found that men may feel distress, especially if they work hard, in the presence of 0.1 per cent. or under of carbon monoxid, when animals at rest in their cages do not distinctly show it. Sometimes different animals of the same species appear to be affected differently by the same proportion of the gas; hence more than one should be used at a time. Fortunately, no acclimatization of canaries appears to occur under the conditions surrounding recovery work in mines, so that these birds do not become less useful or a possible source of danger. They respond promptly to alternate intoxication and resuscitation; whereas guinea-pigs, for example, appear to become somewhat immune. Those who appreciate the seriousness of such situations will realize the advantage of being able by means of animals to define the danger-zone in mines.

THE DEATH-RATE FOR 1913

According to a bulletin of the Bureau of the Census, the death-rate of the registration area of the United States for 1913 was 14.1 per thousand estimated population. In 1912 it was 13.9, in 1911, 14.2. For the years from 1901 to 1905 the average was 16.2; from 1906 to 1910 it was 15.1. We are therefore continuing in improvement, the average for 1911, 1912 and 1913 being 14.06. These are the exact figures as stated in the report of the census bureau. What they mean in actual lives is not indicated except by closer analysis. The decrease from 16.2, the average from 1901 to 1905, to 14.1, the average for 1913, amounts to 13 per cent., or a reduction of one death in every eight. If the same rate had prevailed in 1913 as in the period from 1901 to 1905, there would have been 1,025,446 deaths recorded instead of 890,823, an excess of 134,623.

The largest percentage of decrease was shown for Rhode Island (15.7), followed by New York (12.3), New Jersey (11.2) and Massachusetts (9.6). It seems to be only a peculiar coincidence that these leaders should all be in one small section of the entire territory discussed. Slight increases which occurred in some states (Michigan, 4.5; New Hampshire, 3, and Indiana, 0.8) are believed to be due in some cases to increased accuracy of registration. The state with the lowest death-rate is Washington, with 8.5 deaths per thousand population; and then in the following order come Minnesota, 10.4; Utah, 11.0, and Wisconsin and Colorado, 11.5. The doubtful honor of possessing the highest rates falls to New Hampshire with 17.1; North Carolina, 16.8; Maryland, 16.2; Vermont, 15.8; Maine, 15.3, and Connecticut, Massachusetts, New York and Rhode Island, 15.0. It seems that in the New England states there occurred most of the higher death-rates and most of the improvement from previous years.

It is significant that the four states in the registration area which have a colored population of over 10 per cent., Kentucky, Maryland, North Carolina and Virginia, should average 15.0, while a group with equal population but fewer colored, Wisconsin, Washington, Vermont and Minnesota, averages 11.5.

Among cities of over 100,000 population, Seattle and Spokane lead by far with death-rates of only 8.4 and 8.9, respectively. Portland, Ore., follows with a rate of 9.5, so that this particular corner of the United States by comparison would seem to be more than holding its own. It seems almost obvious that location, climate and character of population are responsible for this low rate. Minneapolis and St. Paul as usual contest for next place with 11.6 and 11, Oakland and Milwaukee following with 12.5 and 12.7. The highest rates occur in Memphis, Tenn., 20.8; Richmond, Va., 20.4; New Orleans, 19.9; Albany, N. Y., 19.8; Baltimore, 18.5; Nashville, Tenn., 17.8; Birmingham, Ala, 17.4; Atlanta, Ga., 17.4, and Washington, D. C., 17.3.

The cause of this high rate in Southern cities has probably often been mentioned and often explained, but we cannot too often point the way to betterment. In the accompanying table, the significant figures need no explanation.

	Death-Rate per 1,000 Population			Increase (+) or Decrease (—) per cent. 1913 as compared with average 1901-1905		
	Total	White	Colored	Total	White	Colored
Memphis	20.8	15.9	28.2	+ 7.2	— 3.6	+23.1
Richmond	20.4	16.7	26.8	—12.8	— 9.7	—15.5
New Orleans ...	19.9	15.6	31.9	—11.2	—18.8	+ 2.9
Baltimore	18.5	16.2	31.0	— 7.5	— 9.0	— 3.1
Nashville	17.8	14.7	24.0	—17.2	—13.5	—18.9
Birmingham	17.4	12.3	25.2	......	......	......
Atlanta	17.4	13.5	25.2	—17.5	—16.2	—14.9
Washington	17.3	14.4	24.4	—15.6	—12.7	—17.3
Average	18.68	14.9	27.08	......	......	......

The arraignment is a startling one, but when comparison is made with previous years, a basis is obtained for hope that progress now started will continue, and much is being done. It is to be noted that in only two instances did the colored rate increase. Recently a conference was held at the call of the Louisiana State Board of Health to consider betterment of hygiene among negroes.[1] Five states and the District of Columbia sent delegates. Eight of the leading negroes of the South were present. Progress has been made and sincere workers are adding impetus to the beginning steps. Another decade should see a more reasonable balance between the rates accorded to the two races.

THE STREPTOCOCCI IN MILK

Living organisms, both great and small, are usually associated with a definite habitat. Conditions of transference arise, however, whereby a species peculiar to a given locality is carried to another place. We can often identify the strangers by observing their behavior and comparing it with the deportment of other known organisms. If, perchance, the characteristics of the invaders become altered through adaptation to the new environment, it is not always easy to identify them.

The bacteria found in milk are indeed a heterogeneous collection, and the true types of milk bacteria are to be sought at the sources of contamination. The fact that certain organisms are frequently found in milk does not necessarily mean that they originate in the udder, but rather directs the search toward the focus of infection from which they find their way into the secretion of the mammary gland. It is known that while the colon group is frequently found in water and milk, its natural habitat is the intestinal tract of warm-blooded animals. The experts of the Dairy Division of the Bureau of Animal Industry in

Washington have been investigating the sources from which the streptococci may gain entrance into milk.[1] The foremost possibilities are: contamination with feces, which must always be considered as a possible source of bacteria in milk, which would undoubtedly include members of the lactic-acid group; the presence, in the herd producing the milk, of one or more cows with infected udders; the mouth, which is known to contain streptococci. The habit of licking the flanks and udder provides a more or less direct connection between the mouth of the cow and the milk-pail.

If it can be accomplished, the hygienic significance of the identification of the bacteria in milk with the species or types constantly found in some of these different sources of contamination must be obvious. Accordingly, the government investigators collected representative cultures of streptococci from milk, bovine feces, the mouths of cows and their udders, and compared the bacteriologic characteristics of these related organisms with each other and with those isolated from milk. In view of the extreme variability of these organisms, such a comparison is anything but easy. Indeed, it was found that the morphology varied with varying conditions and could not be correlated with the source of the culture. On the basis of physiologic manifestations, however, some suggestions were forthcoming. When the milk-cultures were considered individually, it was found that with the exception of two which clearly came from feces, they could be included in one or the other of two groups into which the udder cultures were divided.

Current Comment

THE BIOCHEMISTRY OF BACTERIA

Bacteria are known to resemble other organized forms of cellular protoplasm in a very general way in respect to the essential chemical compounds that enter into their make-up. It has been ascertained that they contain various proteins, nucleic acid derivatives, carbohydrates, phosphatids (lecithins) and representatives of the group of "lipoids" now designated as sterols, of which cholesterol is a familiar example. Bacteria are classified at present on the basis of their behavior in various mediums and also on their tinctorial properties as shown by the reaction with a few widely used stains. Both of these features of bacterial response are essentially chemical; and the differential staining of the micro-organisms is clearly an expression of the occurrence of some unlike chemical compounds in the bodies of the bacteria. We have hitherto referred to Tamura's demonstration that in certain strains, such as the tubercle bacillus and the *Mycobacterium lacticola,* for example, the acid-fast phenomena are associated with the presence of a characteristic substance, the higher alcohol mykol,[1] in place of the more familiar cholesterol. He has now further demonstrated other chemical differences between unlike forms of bacteria, namely, the two species already mentioned and the bacillus of diphtheria, which is biologically and morphologically quite distinct from them.[2] The diphtheria organisms are not "acid-fasts," and accordingly mykol was not found in them. They differ also from the tubercle bacilli and the *Mycobacterium lacticola* with respect to the character of the phosphatids which they yield and in the solubilities of their protein components. The amino-acid units of the latter also show variations, the proteins of the bacillus of diphtheria being, by comparison with others, rich in tyrosin and poor in phenylalanin. In all of the three species investigated, however, the Gram-staining seems to depend on the presence of lipoid substances. Such facts represent a further advance toward a comprehensive knowledge of the structural biochemistry of bacteria.

NULLIFICATION BY AMENDMENT

In spite of the fact that legislation restricting the practice of medicine to those showing adequate training and qualifications can be justified only on the ground of public good, each year, in practically every state in which the legislature meets, the medical practice act of that state is subject to attack from some source. Thus each year it is necessary for those interested in the maintenance of high educational standards to resist the assaults made on the law. One who has watched the course of legislation throughout the country for a number of years is led to wonder why a law clearly in the interest of the public must each year be defended from attack by those interested in breaking down its restrictions. In spite of the agitation against such laws under the pretext that the individual should be allowed "free choice of doctors," it is significant that the attacks on medical practice acts are always inspired and led by those who wish to treat the sick for compensation and not by those who wish the privilege of selecting some unqualified practitioner as an attendant. Another significant fact is that no matter how carefully drawn or how diligently guarded after its passage a medical practice law may be, it is eventually nullified, either partially or completely, by the passage of an amendment or the rendering of a judicial decision modifying the definitions or introducing such exemptions as will make it possible for untrained and unqualified persons to perform, under the authority of the law, the very acts which the law itself was intended to prohibit. This nullification process has occurred repeatedly in different states. No better example of it has recently been observed than the recent amendment of the Massachusetts medical practice act, which resulted in the adoption of the following amendment: "Nothing in this act shall be held to apply to registered pharmacists, registered

dentists or registered optometrists, or to restrain the practice of clairvoyance, hypnotism or mind cure, or to apply to any person who administers to or treats the sick or the suffering by mental or spiritual means without the use of drugs or material remedies." Evidently the belief in Massachusetts in spirits, ghosts and similar superstitions has persisted even since Cotton Mather's day. The legalization by the Massachusetts legislature of the fortune-telling clairvoyants who are being put out of business as swindlers by the police in many of our states is a sad commentary on legislative conditions in a state which was once regarded as the intellectual leader of the nation. Another amendment to the bill defined the practice of medicine so as to restrict it very largely to those claiming to be scientifically educated and qualified physicians. That is, the Massachusetts law has gradually been modified by amendment from a restrictive measure into a definitive law, in which the illegal act consists, not in treating disease without proper qualifications and authority, but in claiming to be what one is not, namely, a legally qualified medical practitioner. Such a definitive law, as has been repeatedly pointed out in THE JOURNAL, has its advantages. It must be clearly recognized by physicians and others interested, however, that a purely definitive law is not restrictive and never can be. The amendment of the Massachusetts act furnishes another interesting chapter in the history of our complicated, contradictory and generally ineffective methods of regulating the practice of medicine by law.

POSSIBLE SOURCES OF ACIDOSIS IN INFANCY

A condition of acidosis in the diseases of early infancy is familiar to the modern pediatrist. It may be relative acidosis due to a deficiency in the supply of alkali at a period when bases are particularly needed to meet the requirements of a growing organism; or the acidosis may be a positive rather than a relative phenomenon and be attributable to a production of undue amounts of acid products which for some reason escape further oxidation or destruction in the economy. In the event of the existence of the latter condition one must call to mind, first of all, those examples of acid compounds that are known to arise under such circumstances. Most familiar are the lower members of the fatty acid series, such as the volatile formic, acetic and butyric acids. We would not imply that these are all uniformly non-metabolizable in the body, for acetic acid and its salts are as a rule readily oxidized. Formic acid, once making its appearance, is not so readily destroyed. To account for the possible origin of such compounds would not be difficult, inasmuch as they frequently represent products of the activity of micro-organisms in the gastro-intestinal canal, which is notably liable to excessive bacterial invasion in the disorders of infancy. So far as these substances escape oxidation they are excreted in the urine. Aron and Franz[1] have examined the urine of numerous sucklings in the Children's Clinic at the University of Breslau, without finding more than merest traces of volatile fatty acids therein. The quantity was not increased by an enrichment of the diet in fats; and even in acute disturbances of nutrition, in dyspepsias and alimentary intoxications, as an accompaniment of which they might have been expected to arise, the results were negative. Another organic acid resistant to metabolic destruction is oxalic acid. It has been realized for some time that this arises as a product of the fermentative decomposition of carbohydrates; and such a mode of origin has been postulated for those cases in which oxaluria could not be explained as the result of the ingestion of food (as rhubarb, spinach, etc.) said to contain considerable preformed oxalic acid.[2] According to Aron and Franz, the urine of infants brought up on such oxalate-free foods as milk and milk mixtures almost invariably contains oxalic acid. This is assumed to have either a fermentative origin in the alimentary canal, or an endogenous one in intermediary metabolism. Additions of cane-sugar or other nutrient carbohydrates to the diet seem to augment somewhat the urinary output of oxalic acid. No increase could be associated, however, with acute nutritive disturbances. The facts, negative and positive, here recorded point to a field for investigation that may yield fruitful suggestion with respect to the etiology of some of the obscure acidoses.

NEW HOUSES AND HEALTH

New houses are constantly offered for rent in large numbers in the United States and real-estate agents are naturally desirous to fill the houses on their lists with tenants as soon as possible. Probably a little investigation would show the desirability in this country of requiring a certificate that a new house will not endanger the health of its occupants before families are allowed to move into it. Such municipal regulations are proving valuable in England. Toward the close of 1912 the Portsmouth (England) corporation decided that thereafter no new building intended for human habitation in that borough should be occupied until it had been certified as sanitary in every respect. Dr. A. Mearns Fraser[3] says: "The principal evil that it will prevent is the occupation of houses before they have had time to dry." He adds: "I would far sooner live in a house with defective drainage than in a damp house; the results from the latter are more insidious in their onset and more difficult to overcome. Dampness undoubtedly greatly favors the incidence of consumption, bronchitis, rheumatism, heart-disease and diphtheria. Probably children are more susceptible to the ill effects of damp houses than adults." The departments of health of our cities might well take up this question. Probably most American municipalities already have the legal power necessary to require such certificates and the question is only one of making the regulation and establishing the custom.

Medical News

ARKANSAS

Colored Physicians Society Holds Meeting.—The State Association of Negro Physicians held its annual meeting in Little Rock, May 6 and 7, and elected the following officers: president, Dr. Steven W. Harrison, Fort Smith; vice-presidents, Drs. Madison M. McBeth, Plum Bayou; Harold H. Phipps, Hot Springs, and J. E. Swayzer, Arkadelphia; recording secretary, Dr. G. H. Frank Morris, Cotton Plant; corresponding secretary, Dr. Alexander H. Brown, Argenta, and treasurer, Dr. R. J. Meddaugh, Little Rock. Little Rock was selected as the place of the next annual meeting.

State Meeting.—The thirty-eighth annual meeting of the Arkansas Medical Society was held in Eldorado, May 19-21, and the following officers were elected: president, Dr. St. Cloud Cooper, Fort Smith; vice-presidents, Drs. Gus. A. Warren, Black Rock; Robert A. Hilton, Eldorado, and Rufus S. Rice, Rogers; secretary, Dr. Clinton P. Meriwether, Little Rock (reelected); treasurer and editor of *The Journal of the Arkansas Medical Society,* Dr. William R. Bathurst, Little Rock (reelected); councilors, second district, Dr. Lorenzo T. Evans, Barren Fork; fourth district, Dr. Edwin C. McMullin, Pine Bluff; sixth district, Dr. Charles A. Archer, De Queen; eighth district, Dr. William A. Snodgrass, Little Rock; tenth district, Dr. Joseph T. Clegg, Siloam Springs; delegate to the American Medical Association, Dr. Robert Caldwell, Little Rock, and alternate, Dr. Joseph T. Clegg, Siloam Springs. Little Rock was selected as the place of the next meeting in May, 1915. Resolutions were adopted discontinuing the annual banquet at the society meeting, and placing a suitable memorial tablet in the state sanatorium, Boonville, in commemoration of the work of Dr. John L. Shibley, who initiated the crusade against tuberculosis in Arkansas.

FLORIDA

State Association Meeting.—At the forty-first annual meeting of the Florida Medical Association held in Orlando, May 13-15, the following officers were elected: president, Dr. F. Clinton Moor, Tallahassee; vice-presidents, Drs. Calvin D. Christ, Orlando; Thomas Truelson, Tampa, and John A. Simmons, Arcadia; secretary-treasurer, Dr. Graham E. Henson, Jacksonville; librarian, Dr. James D. Pasco, Jacksonville, and delegate to the American Medical Association, Dr. John MacDiar, Deland. Deland was selected as the next place of meeting; and it was decided that the association publish a monthly journal, to stimulate interest in the profession in general, and in the state organization in particular.

ILLINOIS

County Secretaries Elect.—At a meeting of the County Secretaries' Association, held in Decatur, May 19, Dr. Harry F. Bennett, Litchfield, was elected president, Dr. Elizabeth B. Ball, Quincy, vice-president, and Charles W. Carter, Clinton, secretary.

Personal.—Dr. and Mrs. Robert S. Denney, Aurora, sailed for Europe, May 19.——Dr. Thomas J. Whitten, Nokomis, for forty-seven years in practice, has decided to retire, and will reside with his daughter in Peoria.——Dr. Edwin E. Williams, Streator, is reported to be seriously ill.——Dr. Halley A. Smith, a member of the staff of the Rockford Hospital, has entered the Santa Fe System medical service at Topeka.

Failures of 1913 Graduates.—Table "C" published last week in The Journal, on page 1648, in State Board Statistics, contained a clerical error relating to the 1913 graduates of Bennett Medical College. The table shows correctly that of the 100 "graduates of 1909 to 1913" examined during the year, 14 (14 per cent.) failed. The correct figures show, however, that 54 graduates of 1913 were examined, and of these that 3, or 5.6 per cent., failed.

Hospital Notes.—At an informal meeting of the members of the La Salle-Peru Medical Society held in La Salle, recently, a plan for an isolation hospital on the dividing line between the two cities was discussed, and it is understood that the members went on record as favoring the plan.——Sixty physicians of Peru and vicinity met in Peru, May 7, to inspect the new People's Hospital. After the opening, the visiting physicians were entertained at dinner at the Hotel Peru. The institution is a three-story structure, has been erected at a cost of $90,000, and will accommodate fifty patients.

State Society Meeting.—At the annual meeting of the Illinois State Medical Society, held in Decatur, May 19-21, the following officers were elected: president, Dr. Albert L. Brittin, Athens; president-elect, Dr. Charles W. Lillie, East St. Louis; vice-presidents, Drs. Otto T. Freer, Chicago, and Everett J. Brown, Decatur; secretary, Dr. Wilbur H. Gilmore, Mount Vernon (reelected); treasurer, Dr. A J. Markley, Belvidere (reelected); councilors, first district, Dr. Emil Windmueller, Woodstock; second district, Dr. Edwin S. Gillespie, Wenona; eighth district, Dr. Elmer B. Cooley, Danville; delegates to the American Medical Association, Drs. Guy L. Armstrong, Taylorville; James W. Hamilton, Mount Vernon; Fernando C. Gale, Pekin; William L. Noble, Chicago; Charles P. Caldwell, Chicago, and Henry F. Lewis, Chicago; alternates, Drs. Alden Alguire, Belvidere; Lay G. Burroughs, Collinsville, Frank Buckmaster, Effingham; Frederick Tice, Chicago, Hugh N. MacKechnie, Chicago, and Duncan R. MacMartin, Chicago. Springfield was selected as the place of meeting for 1915, and the date appointed was May 18-20. At the meeting of the House of Delegates, May 19, a gift of $500 was made to Dr. Edmund W. Weis, Ottawa, for sixteen years secretary of the society.

Chicago

Personal.—Dr. and Mrs. Peter C. Schenkelberger, and Dr. Michael Goldenberg have gone abroad.

Council Provides Funds for Crime Investigation.—The city council at its last session passed an appropriation of $10,000 for the work of a special committee on crime, and $1,200 for the survey of the vice control situation to be made by the health committee.

City to Certify Babies.—Chief Justice Harry Olson of the municipal court proposes that the new psychopathic laboratory shall examine all children taken by foster parents from the morals court, and declare them to be normal before they are allowed to pass from the jurisdiction of the court.

Conference for Care of Subnormal.—A conference of Chicago charity workers to devise plans for the care of subnormal children and adults was held recently in the office of the county board. The conference was called because of the emergency which now exists in Illinois owing to the presence of 6,000 subnormals in Chicago and 18,000 in the state of Illinois, in need of institutional care, while the state institutions have a maximum capacity of 1,800.

Bills will be introduced into the next session of the legislature, and conferences will be held to determine the best legislation to be enacted.

The appointment of committees on legislation, propaganda, and to meet the Illinois state board of administration was decided on, but the members were not named. President A. A. McCormick was appointed chairman of the organization committee, which was made permanent.

INDIANA

Medical Library at Gary.—The members of the Gary County Medical Society are making preparations to start a medical library section in the Gary Public Library.

National Guard Changes.—Maj. John J. Boaz, M.C., Ind.N.G., surgeon in charge of the Field Hospital; Capt. John W. Sluss and Lieut. T. B. Victor Keene, all of Indianapolis, have resigned from the Medical Corps of the Indiana National Guard.

Meningitis in Indianapolis.—Twenty-four cases of cerebrospinal meningitis have been reported since January 1. Twelve cases and three deaths have been reported in May. The City Board of Health has urged the reporting of all cases so that a thorough investigation of each one may be made, and requests the cooperation of all physicians in stamping out the disease. Only nine deaths occurred from cerebrospinal meningitis during the year 1913.

Meat Packer Indicted by Grand Jury.—C. J. Gardner, a meat packer who was fined $500 and costs and sentenced to jail for six months after he was found guilty in police court on the charge of having unwholesome and diseased meat in his possession with intent to sell such meat, has been indicted on a similar charge by the Marion County grand jury. The case in police court involved the carcass of a diseased sheep. It is understood the charges on which the indictment is based involves the carcass of a cow.

Hospital Notes.—The Robert W. Long Hospital, Indianapolis, is almost completed and will be dedicated next month. The building has been erected at a cost of $250,000, exclusive of the site, and will be part of the University of Indiana

School of Medicine, and under the control of the faculty of the school. The hospital is the gift of Mr. and Mrs. Robert W. Long.——The new St. Francis Hospital, Beech Grove, will be dedicated with formal ceremonies June 21. The institution, which has been erected at a cost of $200,000, will accommodate 200 patients and will be conducted by the Sisters of St. Francis.

Personal.—Drs. William Osenbach and Frank L. Truitt were attacked with an axe during a neighborhood quarrel in Indianapolis, May 10.——Dr. Orlando B. Williams, Andrews, who has been seriously ill, is reported to be improving.——Dr. William F. Walsh, Indianapolis, was seriously injured, recently, in a collision between his automobile and a switch engine.——Dr. Algie H. Shock, Silverlake, is reported to be ill with small-pox.——Dr. Earl P. Wagner, South Bend, who has been ill for three weeks, is reported to be convalescent.——Dr. Herschel L. Bass, Ft. Branch, coroner of Gibson County, has resigned and moved to Elberfeld.——Drs. Roscoe L. Sensenich and Stanley A. Clark, South Bend, have been appointed trustees of the County Anti-Tuberculosis Camp.——Dr. Robert W. Harris has been elected president and Dr. Anna I. McKamp, secretary, and Dr. Elihu P. Easley a trustee of the Floyd County Hospital Association. The object of the organization is to promote the erection of a tuberculosis sanatorium on the "knobs" back of New Albany.

IOWA

Personal.—Dr. Bert A. Bowers and family, Granville, have gone abroad.——Dr. Cyrus O. Callison, Albion, was seriously injured by the overturning of his automobile, May 12.——Dr. Thomas E. Powers, Clarinda, is reported to be ill with diphtheria.

Sanatorium News.—Scott County Tuberculosis Sanatorium, Davenport, is nearly completed, and will be ready for occupancy June 15. The buildings have been erected at a cost of $75,000, and the institution will be able to accommodate forty patients.

State Society Meeting.—The annual meeting of the Iowa State Medical Society was held in Sioux City, May 13-15, under the presidency of Dr. Lee W. Dean, Iowa City. The following officers were elected: president, Dr. Henry C. Eschbach, Albia; vice-presidents, Drs. David W. Smouse, Des Moines, and John F. Herrick, Ottumwa; secretary, Dr. James W. Osborn, Des Moines (reelected); treasurer, Dr. William B. Small, Waterloo; editor, Dr. David S. Fairchild, Clinton; councilors: second district, Dr. Henry Albert, Iowa City; third district, Dr. Joseph C. Powers, Hampton; fourth district, Dr. Paul E. Gardner, New Hampton; seventh district, Dr. Corwin W. Cornell, Knoxville; eighth district, Dr. J. Frank Aldrich, Shenandoah; delegates to the American Medical Association, Drs. Lawrence W. Littig, Davenport; Mathew N. Voldeng, Cherokee, and John C. Rockafellow, Des Moines; and alternates, Drs. Walter L. Bierring, Des Moines; Daniel H. Bowen, Waukon, and Charles S. James, Centerville. Waterloo was decided on as the next place of meeting for 1915. The House of Delegates decided to purchase the *Iowa Medical Journal* from Dr. Edward Dorr, Des Moines, for $1,000. This offer includes the exchange, advertising and subscription lists and the good-will of the publication.

MASSACHUSETTS

Testimonial to State Health Officer.—The term of service of Dr. Henry Pickering Walcott, Boston, for thirty-three years health officer and chairman of the State Board of Health, terminated May 19. On the occasion of his retirement, an address was presented to him, signed by 2,200 members of the medical profession of Massachusetts. The address sets forth the public health work done by Dr. Walcott, his establishment of a laboratory for the free production and distribution of diphtheria antitoxin, the establishment through his influence of a laboratory for the preparation of antitoxins and animal vaccines, and the many improvements in sanitary conditions carried out under his recommendation, and other great and grave problems of sanitation and hygiene, and closes with the following eulogium: "You have met the responsibilities which you have assumed with such wisdom, discretion, and rare modesty, as to make the task of your successor who would uphold the standard bequeathed to him, a difficult one indeed."

MICHIGAN

Personal.—Dr. Philip D. Bourland has succeeded Dr J. M. P. Pichette as health officer of Lake Linden.——Dr. William L. Hircik, Whitehall, is reported to be seriously ill with diphtheria.

New Sanitarium.—Dr. Thomas Bennett O'Keefe, Grand Rapids, will build a new sanitarium building, three stories and a basement in height, adjoining the present building at Reed's Lake. The new building will cost $20,000, will accommodate fifty patients, and will be completed in the early autumn.

New Officers.—Southwestern Michigan Medical Society, made up of specialists in diseases of the eye, ear, nose and throat, of Battle Creek, Kalamazoo, Grand Rapids, Lansing and Muskegon, at Battle Creek, May 4: president, Dr. Edward J. Bernstein, Kalamazoo; secretary-treasurer, Dr. Wilfrid Haughey, Battle Creek.

MINNESOTA

Tag-Day in Duluth.—On May 16 the Women of Linnaea Society held a tag-day for the aid of tuberculosis sufferers, as a result of which $1,000 was realized.

Range Physicians Organize.—At a meeting of the physicians of Mesaba Range held in Virginia, May 11, the Range Medical Association was organized, with the following officers: president, Dr. John C. Farmer, McKinley; vice-president, Dr. Charles B. Lenont, Virginia, and secretary, Dr. Henry E. Michelson, Virginia.

MISSISSIPPI

Fever Detains Steamer.—The British steamer *Carisbrook*, from Tela, British Honduras, to Gulfport, with ballast, was detained at the quarantine station, Ship Island, on account of several cases of fever among the crew.

Colored Physicians Hold Meeting.—At the annual meeting of the Colored Medical, Dental and Pharmaceutical Association of Mississippi, held in Jackson, April 29 and 30, Dr. Daniel W. Sherrod, Meridian, was elected president; W. M. P. Harris, Vicksburg, vice-president; Dr. Lemon R. Young, Hattiesburg, secretary; and B. W. Turner, treasurer. Meridian was selected as the next place of meeting.

Pellagra in 1913.—During the first nine months of 1913, according to the report of the State Board of Health, there were 3,734 cases of pellagra reported, of which 1,689 were white and 2,045 colored. The deaths were 544, of which 106 were of whites and 406 colored. This represented 3.6 per cent. of the total deaths, 2.6 per cent. of white deaths and 4.2 colored, a ratio of nearly two to one. During the entire year the deaths were 795. It is believed that more accurate statistics would somewhat increase this figure.

MISSOURI

New State Society Officers.—At the fifty-seventh annual meeting of the Missouri State Medical Association held at Joplin, May 12-14, the following officers were elected: president, Dr. Henry C. Shuttee, Westplains; vice-presidents, Drs. James A. McComb, Lebanon; Godfrey O. Cuppaidge, Moberly; William G. Estill, Lawson; Theodore A. Coffelt, Springfield, and William A. Clark, Jefferson City; secretary and editor, Dr. Edward J. Goodwin, St. Louis (reelected); treasurer, Dr. Franklin Welch, Salisbury (reelected); councilors, sixteenth district, Dr. Harry S. Crawford, Harrisonville; nineteenth district, Dr. Stephen V. Bedford, Jefferson City; twenty-second district, Dr. Garnett S. Cannon, Fornfelt; twenty-sixth district, Dr. William H. Breuer, St. James; twenty-seventh district, Dr. James H. Elliott, Westplains; twenty-eighth district, Dr. Thomas O. Klinger, Springfield; twenty-ninth district, Dr. Robert L. Wills, Neosho; delegates to the American Medical Association, Drs. Enoch H. Miller, Liberty; Andrew W. McAlister, Jr., Kansas City; Henry L. Reid, Charleston; Edward J. Goodwin, St. Louis, and Robert M. Funkhouser, St. Louis. The next meeting will be held in St. Joseph.

NEBRASKA

Personal.—Dr. Samuel K. Spalding, Omaha, has been elected medical director of the Department of Nebraska G. A. R.——Dr. Albert J. Coats, Fairbury, sails for Germany, June 26.

State Society Meeting.—At the annual meeting of the Nebraska State Medical Society in Lincoln, May 12-14, the following officers were elected: president, Dr. John P. Gilligan, O'Neill; vice-presidents, Drs. Leander B. Smith, Fremont, and John I. McGirr, Beatrice; delegate to the American Medical Association, Dr. Artemas I. MacKinnon, Lincoln; and alternate, Dr. Burton W. Christie, Omaha. There was a registration of 300 members at the general session. On April 30, 767 members had paid their 1914 dues leaving over

Hospital Notes.—At an informal meeting of the members of the La Salle-Peru Medical Society held in La Salle, recently, a plan for an isolation hospital on the dividing line between the two cities was discussed, and it is understood that the members went on record as favoring the plan.——Sixty physicians of Peru and vicinity met in Peru, May 7, to inspect the new People's Hospital. After the opening, the visiting physicians were entertained at dinner at the Hotel Peru. The institution is a three-story structure, has been erected at a cost of $90,000, and will accommodate fifty patients.

State Society Meeting.—At the annual meeting of the Illinois State Medical Society, held in Decatur, May 19-21, the following officers were elected: president, Dr. Albert L. Brittin, Athens; president-elect, Dr. Charles W. Lillie, East St. Louis; vice-presidents, Drs. Otto T. Freer, Chicago, and Everett J. Brown, Decatur; secretary, Dr. Wilbur H. Gilmore, Mount Vernon (reelected); treasurer, Dr. A J. Markley, Belvidere (reelected); councilors, first district, Dr. Emil Windmueller, Woodstock; second district, Dr. Edwin S. Gillespie, Wenona; eighth district, Dr. Elmer B. Cooley, Danville; delegates to the American Medical Association, Drs. Guy L. Armstrong, Taylorville; James W. Hamilton, Mount Vernon; Fernando C. Gale, Pekin; William L. Noble, Chicago; Charles P. Caldwell, Chicago, and Henry F. Lewis, Chicago; alternates, Drs. Alden Alguire, Belvidere; Lay G. Burroughs, Collinsville, Frank Buckmaster, Effingham; Frederick Tice, Chicago, Hugh N. MacKechnie, Chicago, and Duncan R. MacMartin, Chicago. Springfield was selected as the place of meeting for 1915, and the date appointed was May 18-20. At the meeting of the House of Delegates, May 19, a gift of $500 was made to Dr. Edmund W. Weis, Ottawa, for sixteen years secretary of the society.

Chicago

Personal.—Dr. and Mrs. Peter C. Schenkelberger, and Dr. Michael Goldenberg have gone abroad.

Council Provides Funds for Crime Investigation—The city council at its last session passed an appropriation of $10,000 for the work of a special committee on crime, and $1,200 for the survey of the vice control situation to be made by the health committee.

City to Certify Babies.—Chief Justice Harry Olson of the municipal court proposes that the new psychopathic laboratory shall examine all children taken by foster parents from the morals court, and declare them to be normal before they are allowed to pass from the jurisdiction of the court.

Conference for Care of Subnormal.—A conference of Chicago charity workers to devise plans for the care of subnormal children and adults was held recently in the office of the county board. The conference was called because of the emergency which now exists in Illinois owing to the presence of 6,000 subnormals in Chicago and 18,000 in the state of Illinois, in need of institutional care, while the state institutions have a maximum capacity of 1,800.

Bills will be introduced into the next session of the legislature, and conferences will be held to determine the best legislation to be enacted.

The appointment of committees on legislation, propaganda, and to meet the Illinois state board of administration was decided on, but the members were not named. President A. A. McCormick was appointed chairman of the organization committee, which was made permanent.

INDIANA

Medical Library at Gary.—The members of the Gary County Medical Society are making preparations to start a medical library section in the Gary Public Library.

National Guard Changes.—Maj. John J. Boaz, M.C., Ind.N.G., surgeon in charge of the Field Hospital; Capt. John W. Sluss and Lieut. T. B. Victor Keene, all of Indianapolis, have resigned from the Medical Corps of the Indiana National Guard.

Meningitis in Indianapolis.—Twenty-four cases of cerebrospinal meningitis have been reported since January 1. Twelve cases and three deaths have been reported in May. The City Board of Health has urged the reporting of all cases so that a thorough investigation of each one may be made, and requests the cooperation of all physicians in stamping out the disease. Only nine deaths occurred from cerebrospinal meningitis during the year 1913.

Meat Packer Indicted by Grand Jury.—C. J. Gardner, a meat packer who was fined $500 and costs and sentenced to jail for six months after he was found guilty in police court on the charge of having unwholesome and diseased meat in his possession with intent to sell such meat, has been indicted on a similar charge by the Marion County grand jury. The case in police court involved the carcass of a diseased sheep. It is understood the charges on which the indictment is based involves the carcass of a cow.

Hospital Notes.—The Robert W. Long Hospital, Indianapolis, is almost completed and will be dedicated next month. The building has been erected at a cost of $250,000, exclusive of the site, and will be part of the University of Indiana

School of Medicine, and under the control of the faculty of the school. The hospital is the gift of Mr. and Mrs. Robert W. Long.——The new St. Francis Hospital, Beech Grove, will be dedicated with formal ceremonies June 21. The institution, which has been erected at a cost of $200,000, will accommodate 200 patients and will be conducted by the Sisters of St. Francis.

Personal.—Drs. William Osenbach and Frank L. Truitt were attacked with an axe during a neighborhood quarrel in Indianapolis, May 10.——Dr. Orlando B. Williams, Andrews, who has been seriously ill, is reported to be improving.——Dr. William F. Walsh, Indianapolis, was seriously injured, recently, in a collision between his automobile and a switch engine.——Dr. Algie H. Shock, Silverlake, is reported to be ill with small-pox.——Dr. Earl P. Wagner, South Bend, who has been ill for three weeks, is reported to be convalescent.——Dr. Herschel L. Bass, Ft. Branch, coroner of Gibson County, has resigned and moved to Elberfeld.——Drs. Roscoe L. Sensenich and Stanley A. Clark, South Bend, have been appointed trustees of the County Anti-Tuberculosis Camp.——Dr. Robert W. Harris has been elected president and Dr. Anna I. McKamp, secretary, and Dr. Elihu P. Easley a trustee of the Floyd County Hospital Association. The object of the organization is to promote the erection of a tuberculosis sanatorium on the "knobs" back of New Albany.

IOWA

Personal.—Dr. Bert A. Bowers and family, Granville, have gone abroad.——Dr. Cyrus O. Callison, Albion, was seriously injured by the overturning of his automobile, May 12.——Dr. Thomas E. Powers, Clarinda, is reported to be ill with diphtheria.

Sanatorium News.—Scott County Tuberculosis Sanatorium, Davenport, is nearly completed, and will be ready for occupancy June 15. The buildings have been erected at a cost of $75,000, and the institution will be able to accommodate forty patients.

State Society Meeting.—The annual meeting of the Iowa State Medical Society was held in Sioux City, May 13-15, under the presidency of Dr. Lee W. Dean, Iowa City. The following officers were elected: president, Dr. Henry C. Eschbach, Albia; vice-presidents, Drs. David W. Smouse, Des Moines, and John F. Herrick, Ottumwa; secretary, Dr. James W. Osborn, Des Moines (reelected); treasurer, Dr. William B. Small, Waterloo; editor, Dr. David S. Fairchild, Clinton; councilors: second district, Dr. Henry Albert, Iowa City; third district, Dr. Joseph C. Powers, Hampton; fourth district, Dr. Paul E. Gardner, New Hampton; seventh district, Dr. Corwin W. Cornell, Knoxville; eighth district, Dr. J. Frank Aldrich, Shenandoah; delegates to the American Medical Association, Drs. Lawrence W. Littig, Davenport; Mathew N. Voldeng, Cherokee, and John C. Rockafellow, Des Moines; and alternates, Drs. Walter L. Bierring, Des Moines; Daniel H. Bowen, Waukon, and Charles S. James, Centerville. Waterloo was decided on as the next place of meeting for 1915. The House of Delegates decided to purchase the *Iowa Medical Journal* from Dr. Edward Dorr, Des Moines, for $1,000. This offer includes the exchange, advertising and subscription lists and the good-will of the publication.

MASSACHUSETTS

Testimonial to State Health Officer.—The term of service of Dr. Henry Pickering Walcott, Boston, for thirty-three years health officer and chairman of the State Board of Health, terminated May 19. On the occasion of his retirement, an address was presented to him, signed by 2,200 members of the medical profession of Massachusetts. The address sets forth the public health work done by Dr. Walcott, his establishment of a laboratory for the free production and distribution of diphtheria antitoxin, the establishment through his influence of a laboratory for the preparation of antitoxins and animal vaccines, and the many improvements in sanitary conditions carried out under his recommendation, and other great and grave problems of sanitation and hygiene, and closes with the following eulogium: "You have met the responsibilities which you have assumed with such wisdom, discretion, and rare modesty, as to make the task of your successor who would uphold the standard bequeathed to him, a difficult one indeed."

MICHIGAN

Personal.—Dr. Philip D. Bourland has succeeded Dr J. M. P. Pichette as health officer of Lake Linden.——Dr. William L. Hircik, Whitehall, is reported to be seriously ill with diphtheria.

New Sanitarium.—Dr. Thomas Bennett O'Keefe, Grand Rapids, will build a new sanitarium building, three stories and a basement in height, adjoining the present building at Reed's Lake. The new building will cost $20,000, will accommodate fifty patients, and will be completed in the early autumn.

New Officers.—Southwestern Michigan Medical Society, made up of specialists in diseases of the eye, ear, nose and throat, of Battle Creek, Kalamazoo, Grand Rapids, Lansing and Muskegon, at Battle Creek, May 4: president, Dr. Edward J. Bernstein, Kalamazoo; secretary-treasurer, Dr. Wilfrid Haughey, Battle Creek.

MINNESOTA

Tag-Day in Duluth.—On May 16 the Women of Linnaea Society held a tag-day for the aid of tuberculosis sufferers, as a result of which $1,000 was realized.

Range Physicians Organize.—At a meeting of the physicians of Mesaba Range held in Virginia, May 11, the Range Medical Association was organized, with the following officers: president, Dr. John C. Farmer, McKinley; vice-president, Dr. Charles B. Lenont, Virginia, and secretary, Dr. Henry E. Michelson, Virginia.

MISSISSIPPI

Fever Detains Steamer.—The British steamer *Carisbrook*, from Tela, British Honduras, to Gulfport, with ballast, was detained at the quarantine station, Ship Island, on account of several cases of fever among the crew.

Colored Physicians Hold Meeting.—At the annual meeting of the Colored Medical, Dental and Pharmaceutical Association of Mississippi, held in Jackson, April 29 and 30, Dr. Daniel W. Sherrod, Meridian, was elected president; W. M. P. Harris, Vicksburg, vice-president; Dr. Lemon R. Young, Hattiesburg, secretary; and B. W. Turner, treasurer. Meridian was selected as the next place of meeting.

Pellagra in 1913.—During the first nine months of 1913, according to the report of the State Board of Health, there were 3,734 cases of pellagra reported, of which 1,689 were white and 2,045 colored. The deaths were 544, of which 106 were of whites and 406 colored. This represented 3.6 per cent. of the total deaths, 2.6 per cent. of white deaths and 4.2 colored, a ratio of nearly two to one. During the entire year the deaths were 795. It is believed that more accurate statistics would somewhat increase this figure.

MISSOURI

New State Society Officers.—At the fifty-seventh annual meeting of the Missouri State Medical Association held at Joplin, May 12-14, the following officers were elected: president, Dr. Henry C. Shuttee, Westplains; vice-presidents, Drs. James A. McComb, Lebanon; Godfrey O. Cuppaidge, Moberly; William G. Estill, Lawson; Theodore A. Coffelt, Springfield, and William A. Clark, Jefferson City; secretary and editor, Dr. Edward J. Goodwin, St. Louis (reelected); treasurer, Dr. Franklin Welch, Salisbury (reelected); councilors, sixteenth district, Dr. Harry S. Crawford, Harrisonville; nineteenth district, Dr. Stephen V. Bedford, Jefferson City; twenty-second district, Dr. Garnett S. Cannon, Fornfelt; twenty-sixth district, Dr. William H. Breuer, St. James; twenty-seventh district, Dr. James H. Elliott, Westplains; twenty-eighth district, Dr. Thomas O. Klinger, Springfield; twenty-ninth district, Dr. Robert L. Wills, Neosho; delegates to the American Medical Association, Drs. Enoch H. Miller, Liberty; Andrew W. McAlister, Jr., Kansas City; Henry L. Reid, Charleston; Edward J. Goodwin, St. Louis, and Robert M. Funkhouser, St. Louis. The next meeting will be held in St. Joseph.

NEBRASKA

Personal.—Dr. Samuel K. Spalding, Omaha, has been elected medical director of the Department of Nebraska G. A. R.——Dr. Albert J. Coats, Fairbury, sails for Germany, June 26.

State Society Meeting.—At the annual meeting of the Nebraska State Medical Society in Lincoln, May 12-14, the following officers were elected: president, Dr. John P. Gilligan, O'Neill; vice-presidents, Drs. Leander B. Smith, Fremont, and John I. McGirr, Beatrice; delegate to the American Medical Association, Dr. Artemas I. MacKinnon, Lincoln; and alternate, Dr. Burton W. Christie, Omaha. There was a registration of 300 members at the general session. On April 30, 767 members had paid their 1914 dues leaving over

200 delinquents. A local committee of Lancaster County physicians secured a very suitable convention hall and committee rooms for the meetings. The social features were entertaining, instructive and unexcelled—if ever equaled—at any prior state association convention. By a majority vote of the house an invitation to hold the next annual convention in Hastings, Neb., was accepted.

NEW HAMPSHIRE

State Society Meeting.—The one hundred and twenty-third annual meeting of the New Hampshire Medical Society was held in Concord, May 13-15, under the presidency of Dr. Abram W. Mitchell, Epping. Dr. Charles F. Flanders, Manchester, presided over the medical section, and Dr. John M. Gile, Hanover, over the surgical section. The following officers were elected: president, Dr. Herbert K. Faulkner, Keene; secretary, Dr. Dennis E. Sullivan, Concord (reelected); councilors, Drs. Charles S. Walker, Keene; and Emery M. Fitch, Claremont; trustee, Dr. John M. Gile, Hanover; delegates to the American Medical Association, Dr. Irving A. Watson, Concord, and alternate, Dr. George W. McGregor, Littleton. Drs. John F. Robinson and George S. Foster, Manchester, were recommended to the governor as members of the Regular Board of Medical Examiners.

NEW JERSEY

Atlantic City Number.—The descriptive article on "The Charms of the Convention City" which appeared in the Atlantic City Number of The Journal was contributed almost wholly by Dr. C. C. Charlton.

New Hospital Directors.—The Camden County Board of Free Holders on May 13 appointed the following to take charge of the new tuberculosis hospital at Ancora: Drs. J. W. Schellenger, Joseph E. Roberts, Jr., Camden, Morgan Solly, Addison B. Reder, Camden, and John I. Hoverton.

Relief Society Election.—The thirty-second annual meeting of the Relief Society for Widows and Orphans of Medical Men of New Jersey was held in Newark, May 13, and the following officers were elected: president, Dr. Edward J. Ill, Newark; vice-president, Dr. Norton L. Wilson, Elizabeth; secretary, Dr. Charles D. Bennett, Newark; treasurer, Dr. Harold A. Tarbell, Newark, and trustees, Drs. Gordon K. Dickinson, Jersey City; Frank M. Child, Hoboken, and Christopher C. Beling, Newark.

NEW YORK

Personal.—Dr. Leverett D. Bristol, Syracuse, has been appointed head of the public health laboratory of the University of North Dakota.——Drs. S. W. Gill Wylie and Adolf Rostenberg have sailed for Europe.

Harrington Lectures.—The Harrington lectures of the Medical Department of the University of Buffalo will be delivered by Prof. Ludwig Pick, Berlin, Germany, on the evening of June 2, and the afternoon of June 2 and 3. The *subject of the lectures will be* "Some Recent Advances in Pathologic Anatomy." The lecture will be illustrated by lantern-slides and many lumière plates.

Buys Site for Hospital.—It is announced that the Beth Israel Association has made public its plans for the construction of one of the largest private hospitals in the city. The site purchased is on Livingston Place, facing Stuyvesant Square and contains 14,000 square feet. A sixteen story hospital building will be erected at a cost of $1,000,000. The new hospital will provide for 500 patients and will be the last word in hospital construction and equipment.

New York City

Street Accidents in Greater New York.—*During the year* 1913 in the streets of the Greater City there were 119 persons killed by trolleys, 169 by horse-drawn vehicles and 109 by automobiles.

Vaccination Stations.—The Department of Health has arranged to have small-pox vaccination performed daily in all the children's clinics of the department and also on two days of each week at each infant's milk station. This action will create sixty-two offices of the department where vaccination may be obtained free of charge.

Personal.—Dr. Otto Glogau has been appointed delegate to the Third International Congress on Occupational Diseases, to be held in Vienna in September next.——Dr. and Mrs. William Lintz, Brooklyn, sailed for Europe, May 16.

Hospital Reorganization Urged.—At the fifth annual City Conference of Charities and Corrections, which was in session May 19 and 20, Dr. Sigismund S. Goldwater outlined an improved plan for the hospital service of the city. Dr. Goldwater opposes the expansion of hospitals as health centers, holding that this work is preventive and belongs to the province of the Health Department. He thought that either a large board of trustees, a smaller board, or a single commissioner might satisfactorily administer the city hospitals. Nine ideally organized hospitals distributed among three city departments in groups of three would *serve the city better than nine hospitals improperly organized*, but under single control. The project to put all hospitals of the city under a new department of hospitals was received with favor by those who had recently made an investigation of the city hospitals for the mayor.

NORTH DAKOTA

Personal.—Dr. George A. Stark, Mandan, is critically ill as a result of a cerebral hemorrhage.——Dr. William H. Witherstine, Grand Forks, has been appointed county coroner, vice Dr. Francis E. Murphy.

Conservation of Vision.—Dr. John H. Rindlaub of Fargo has been selected as lecture bureau manager in connection with the lectures on the conservation of vision provided for under the auspices of the Council on Health and Public Instruction of the American Medical Association. It is hoped to have delivered at least one lecture a year in each county in the state. These lectures will cover the subjects of ophthalmia neonatorum, the medical inspection of schoolchildren, the prevention of eye injuries in shops and factories, proper illumination of schools, halls, trains, etc., the prevention and spread of trachoma and some others. Gonorrhea is a reportable disease in North Dakota.

New Officers of State Society.—At the annual meeting of the North Dakota Medical Association, held in Grand Forks, May 13 and 14, the following officers were elected: president, Dr. R. Hudson Beek, Lakota; vice-presidents, Drs. Victor J. La Rose, Bismarck, and George M. Williamson, Grand Forks; secretary, Dr. Hezekiah J. Rowe, Casselton (reelected); treasurer, Dr. Charles S. Crane, Grand Forks; councilors, Drs. George A. Carpenter, Fargo; Robert D. Campbell, Grand Forks; and Francis R. Smyth, Bismarck; and delegate to the American Medical Association, Dr. Charles S. Crane, Grand Forks, vice Dr. James Grassick, Grand Forks. Bismarck was selected as the next place of meeting. The society recommended the following members to the State Examining Board: Drs. Alexander J. McCannel, Minot; Paul Sorkness, Fargo; and John E. Countryman, Grafton.

OKLAHOMA

Personal.—Dr. Samuel W. Wilson, Lindsay, who has been ill with rheumatism, is said to be improving.——Dr. Dumont D. Howell, Nowata, was thrown from a buggy recently, fracturing his left leg above the ankle.——Dr. James P. McRae, Bromide, has been *completely exonerated of blame* following the death of B. B. Askew, Bromide, from alleged strychnin poisoning.——Dr. Roy A. Morter, Norman, has been appointed a member of the staff of the Michigan State Hospital, Kalamazoo, and has been assigned to duty in the women's department.——The offices of Drs. David M. and R. L. Montgomery, Marlow, were destroyed by fire recently.

Hospital Notes.—It is announced that a sanatorium for tuberculosis will be opened in Tahlequah in a short time.——The Sisters of Charity at McAlester have purchased the Cornish property, and will open it as a hospital.——Dr. J. Clay Williams has purchased the building of Dr. Elmer E. Lumm, Stroud, and will fit up the upper rooms of the building for a sanatorium, with accommodations for ten patients.——Fire at the Alva Hospital, recently, caused damage to the extent of $500. The patients were removed without casualty.——Work has been commenced on the new Indian hospital at Lawton, which is to cost $40,000. The building will be ready for occupancy this fall.

State Association Meeting.—The twenty-second annual meeting of the Oklahoma State Medical Association was held in Guthrie, May 12-14, under the presidency of Dr. James M. Byrum, Shawnee. The following officers were elected: president, Dr. John W. Riley, Oklahoma City; vice-presidents, Drs. Charles R. Hume, Anadarko, and Edward F. Davis, Oklahoma City; secretary-treasurer and editor, Dr. Claude A. Thompson, Muskogee (reelected); councilors, first district, composed of Cimarron, Texas, Beaver, Harper, Ellis, Woods and Woodward counties, Dr. R. A. Workman, Woodward; second district, composed of Roger Mills, Becham, Washita, Custer, Dewey, Blaine counties, Dr. Ellis Lamb, Clinton; third district, composed of Harmon, Jackson, Greer, Kiowa, Tillman, Comanche and Cotton counties, Dr. Samuel P. Rawls, Altus; fourth district, composed of Alfalfa, Grant, Garfield, Major, Kay and Noble counties, Dr. Walter H. McKenzie, Enid; fifth district, composed of Kingfisher, Logan, Oklahoma and Canadian counties, Dr. Fred Y. Cronk, Guthrie; sixth district, composed of Caddo, Grady, Stephens, McClain, Garvin and Jefferson counties, Dr. Clinton M. Maupin, Waurika; seventh district, composed of Osage, Pawnee, Creek, Okfuskee, Okmulgee and Tulsa counties, Dr. Walter E. Wright, Tulsa; eighth district, composed of Cleveland, Payne, Lincoln, Pottawatomie and Seminole counties, Dr. H. Marion Williams, Wellston; ninth district, composed of Coal, Pontotoc, Murray, Johnston, Marshall, Love and Carter counties, Dr. J. T. Slover, Sulphur; tenth district, composed of Washington, Nowata, Rogers, Mayes, Craig, Ottawa and Delaware counties, Dr. Robert L. Mitchell, Vinita; eleventh district, composed of Wagoner, Muskogee, McIntosh, Cherokee, Adair and Haskell counties, Dr. Pleasant P. Nesbitt, Muskogee; twelfth district, composed of Hughes, Pittsburg, Latimer, Sequoyah and Leflore counties, Dr. Leonard S. Willour, McAlester, and thirteenth district, composed of Atoka, Bryan, Choctaw, Pushmataha and McCurtain counties, Dr. John L. Austin, Durant. Among the changes to the constitution and by-laws adopted at this meeting were the following: Giving the president and secretary a full vote in the Council and House of Delegates; making the term of office of secretary three instead of two years; giving the council authority to establish a physician's defense bureau, the entire assessment for membership and protection not to exceed $5 a year; making the number of councilors subjects to change by the House of Delegates. The next meeting will be held in Bartlesville, and the meeting for 1916 in Medicine Park. The Women's Auxiliary held its seventh annual meeting at Guthrie, May 13 and 14. The chief subjects discussed by the physicians' wives were: "How Can We Best Promote Interest in, and Establish Auxiliaries to the County Societies, and in What Way Can We, as an Organized Body, be of the Greatest Assistance to the Physicians and the Public" and "The Rights of the Physician's Wife."

PENNSYLVANIA

Rules against Hospital Noises.—The supreme court of Pennsylvania, May 19, sustained a decree handed down by the lower court, ordering the operating-room in the Homeopathic Medical and Surgical Hospital of Reading to be removed to another part of the building, as it was shown the noises therefrom were annoying to the neighbors.

Typhoid Due to Coatesville.—Five children of the Embreeville School in Newlin Township, Chester County, developed typhoid within two days, and in tracing the cause of the outbreak it was found that the school water-supply was obtained from a farm, one-eighth of a mile from the schoolhouse. As the water had to be carried, it was thought the boys have been filling the water buckets at the Brandywine Creek. The sewage from Coatesville, where several cases of typhoid have recently existed, is emptied into this stream without treatment. At a conference of the citizens of Coatesville and the state health commissioner in Harrisburg, May 22, regarding a new water-supply, Dr. Samuel G. Dixon, Harrisburg, thereon requested Attorney General Bell to begin suit against the borough of Coatesville under the act of 1905 for failing to file plans of the existing system of sewers and plans for a sewage disposal plant.

Philadelphia

Alumnae to Meet.—The Alumnae Association of the Women's Medical College of Pennsylvania, Philadelphia, will hold its thirty-ninth annual meeting at the college building, North College Avenue and Twenty-First Street, June 4 and 5, under the presidency of Dr. Eleanor C. Jones. The annual reception and dinner will be held June 4 at the Bellevue-Stratford.

TEXAS

No Quarantine Changes.—Governor Colquitt, after conferring with State Health Officer Steiner, announced, May 4, that there would be no change in the quarantine regulations for Galveston, so far as refugees from main points were concerned.

Roentgenologists Organize.—The Texas Roentgen-Ray Association was organized at Houston, May 14, and the following officers were elected: president, Dr. George D. Bond, Fort Worth; vice-president, Dr. William O. Sauermann, Houston; secretary-treasurer, Dr. John W. Torbett, Marlin. The association is to meet each year at the time and place of the state association convention.

Tulane Alumni Meet.—The alumni of Tulane University, in attendance on the convention of the State Medical Association of Texas, held a meeting and banquet, May 13. Dr. Charles C. Green, Houston, was toastmaster, and the following officers were elected: president, Dr. William M. Brumby, San Antonio, vice-president, Dr. Charles C. Green, Houston; and secretary-treasurer, Dr. M. M. Brown, Mexia.

State Association Meeting.—At the forty-eighth annual meeting of the State Medical Association of Texas, held in Houston, May 12-14, the following officers were elected: president, Dr. Frank D. Boyd, Fort Worth; vice-presidents, Drs. Granville T. Hall, Big Springs; Leopold H. Reeves, Decatur, and Khleber H. Beall, Fort Worth; councilors, second district, Dr. Newton J. Phenix, Colorado (reelected); seventh district, Dr. Thomas J. Bennett, Austin (reelected); eighth district, Dr. Walter Shropshire, Yoakum, (reelected); ninth district, Dr. W. Wallace Ralston, Houston (reelected); tenth district, Dr. Arthur R. Sholars; fourteenth district, Dr. Alva W Carnes, Hutchins; trustee, Dr. R. R. White, Temple, to succeed Dr. John S. Lankford, San Antonio, term expired; delegates to the American Medical Association, Dr. Charles E. Cantrell, Greenville, and Marvin L. Graves, Galveston; alternates, Drs. Witten B. Russ, San Antonio, and Albert Woldert, Tyler. Fort Worth was selected as the next place of meeting.——A Council on Medical Defense, for the purpose of investigating and defending all damage suits against members of the profession, was created by the House of Delegates, May 13.——A resolution was introduced providing that the president appoint a committee to look into the question of providing for indigent members of the association, with a view to establishing a home for such members.——A resolution was introduced providing for the appointment of a committee to formulate a list of drugs which should not be sold except on prescription of a physician was adopted.——A resolution was introduced by Dr. Joseph E. Dildy, Lampasas, providing for the recommendation of the enactment of a law to protect children of the state from disease, by medical inspection of schoolchildren and such other means as may be decided on.——On May 12 memorial exercises were held by the association in honor of members who had died during the last year.

WEST VIRGINIA

Personal.—Dr. Edgar B. Plant has been appointed physician of Ohio County.——Dr. A. Maywood Forsythe, Maynard, who has been seriously ill with pneumonia, is reported to be improving.

Anti-Tuberculosis League Organized.—The Anti-Tuberculosis League of Kanawha County has been incorporated at Charleston by George S. Laidley, F. M. Staunton, Louise F. Jackson, Ethel Ruffner and Virginia A. Payne.

State Society Meeting.—The annual meeting of the West Virginia Medical Society was held in Bluefield, May 13-15, and the following officers were elected: president, Dr. Henry P. Linsz, Wheeling; vice-presidents, Drs. Joseph B. Kirk, Elkhorn, Theodore K. Oates, Martinsburg, and Isaac N. Houston, Moundsville; secretary, Dr. J. Howard Anderson, Marytown; and treasurer, Dr. Hugh G. Nicholson, Charleston; and delegate to the American Medical Association, Dr. Frank L. Hupp, Wheeling. Huntington was selected as the next place of meeting.

WISCONSIN

Personal.—Dr. Albert Jenner, Milwaukee, has sailed for Europe.——Dr. and Mrs. Edward B. Felter, Plymouth, sail for Europe, June 18.

Health Conference Called.—Dr. Cornelius A. Harper, secretary of the State Board of Health, has called a conference of heads of health departments to be held in Madison, June 16 and 17.

Contract for Tuberculosis Camp Awarded.—The State Board of Control has awarded the contract for the construction of the tuberculosis camp on Tomahawk Lake for $8.000. The camp is to be completed by September 1.

New Isolation Hospital.—At a meeting of the members of the State Commission, the County Board of Supervisors and the Douglas County Medical Association, held in Superior, May 13, a campaign was inaugurated for a new city and county isolation hospital.

Sanatorium to Be Used for Insane Patients Only.—Patients of the Douglas County Tuberculosis Sanatorium, Superior, are to be transferred to the Eau Claire or Manitowoc institution, and the hospital will be converted into a state hospital for insane patients afflicted with tuberculosis.

Needs of Emergency Hospital.—Dr. Dennis J. Hayes, president of the Milwaukee County Medical Society, has appointed the following committee of ten to inquire into the needs of an emergency hospital: Drs. Franz Pfister, Lewis G. Nolte, John R. McDill, Albin A. Krygier, Robert G. Sayles, Frederick J. Gaenslen, Frederic C. Gillen, Hubert F. Jermain, Charles H. Lemon and William T. Lochemes.

GENERAL

Anesthetists to Meet.—The second annual meeting of the American Association of Anesthetists will be held at the Hotel Chelsea, Atlantic City, June 22, under the presidency of Dr. J. Tayloe Gwathmey, New York City.

Leper Escapes.—John Early, a leper, has escaped from Diamond Head Quarantine Station, near Port Townsend, Wash. His escape, says Surgeon-General Blue, demonstrates again the necessity of having a national leprosarium.

Examination Date Changed.—An official notice says that the next examination by the State Board of Health of Kentucky has been changed from June 3-5, 1914, to June 15-17, and will be held at the Hotel Henry Watterson, Louisville.

Pennsylvania Surgeons to Meet at Atlantic City.—The annual convention of the Association of Surgeons of the Pennsylvania Lines, East and West of Pittsburgh, will be held at St. Charles Hotel, Atlantic City, June 19 and 20. One of the chief topics of discussion will be the standardizing of methods of treating fractures in railway accidents.

Bequests and Donations.—The following bequests and donations have recently been announced:

Hospital for Deformities and Joint Diseases, New York City, $25,000; Presbyterian, Mount Vernon, and Episcopal hospitals, each $20,000, by the will of Mrs. A. Gertrude Cutter.

Cancer Hospital, and Little Sisters of the Poor, New York City, each $1,000, by the will of Mary F. Kennedy.

New York Foundling Hospital and St. Vincent's Hospital, New York City, each $2,160, by the will of Mary Guerin.

Federated Orthodox Jewish Charities, Chicago, a donation of $1,000 by Samuel Phillipson.

Albany (N. Y.) Medical College, $5,000, by the will of Sylvester McDonald.

FOREIGN

Measures for Suppressing Plague in Japan.—Surgeon B. W. Brown, U. S. P. H. S., on duty at Yokahama, in *Public Health Reports*, May 15, gives a full translation of the regulations adopted for the eradication of plague from the city. He says that during the epidemic of October and November, 1913, in spite of all efforts to stamp it out, twenty-one cases occurred and ninety-nine infected rats were found, and the infection spread to various parts of the city. Money and men were provided and the most thorough measures adopted, and Brown suggests the value of the report to American cities threatened with this infection.

Foot and Mouth Disease in Switzerland.—Consul David F. Wilbur of Zurich has reported that the live-stock and related industries of Switzerland have suffered greatly because of the foot-and-mouth disease, which was present in some of the cantons during the entire year. The cases began to increase and the disease to spread in June, and until the arrival of cold weather in December the ravages of the disease seemed practically uncheckable. It attacked not only cattle, but also to a less extent the hogs, sheep, goats, etc. To combat the spread of the disease the various cantons enacted decrees against neighboring cantons as well as against neighboring foreign countries, which regulated or prohibited the introduction of all live stock into their respective territories. In this way all traffic and trade in live stock was not only greatly hindered, but in some instances it was entirely forbidden.

Deaths in the Profession Abroad.—Bonner Harris Mumby, M.D., Aberdeen, 1881; for eighteen years medical superintendent of the borough asylum, Portsmouth, England; and a member of the Council of the British Medical Association; died suddenly in a motor car between Portsmouth and Southampton, April 29, from angina pectoris.——John Abercrombie, M.D., Cantab, 1880; F.R.C.P.Lond., 1886; consulting physician to Charing Cross Hospital and the Foundling Hospital, London; for several years editor of the Medical Times and Gazette; a specialist in diseases of children; died at his home in Brough, Westmoreland about April 30, from heart disease.——H. v. Wyss, privat-docent for internal medicine at the University of Zurich, aged 33. His publications on metabolism have been valuable. His latest research was on the development of edema under the influence of sodium bicarbonate and he had collected extensive data which he was able only partially to utilize.——A. Pasquale, professor of tropical pathology at the University of Naples and chief of the Scuola d'Igiene Navale and Scuola di Sanita marittima at that place.

CANADA

Floating Hospital.—A floating hospital on the St. Lawrence River is the plan for the reduction of infant mortality during the summer months. It will accommodate about 150 children at a time, and will be reserved for those actually sick. The age limit will be 5 years.

New Department of Analysis.—Montreal is creating a department of analysis. It will be entirely independent of the medical health department and will be a municipal chemical and bacteriology department, under the charge of Dr. Henri St. George, who has been in the employ of the city for eight years.

For Betterment of Health Department.—Dr. Séraphin Boucher, municipal health officer of Montreal, has asked for an appropriation of $5,000, to put the department on a more efficient basis. The plans include the appointment of more efficient sanitary and food inspectors, and the establishment of a civic laboratory, for the analysis of food and other commodities, by an efficient staff.

Physicians Resign.—Nine Montreal physicians have withdrawn from the Herzl Institute, a benevolent medical dispensary for the Jewish population of Montreal. Recently a new directorate was appointed, who immediately proceeded to appoint a new medical board or staff. The retiring staff threatens proceedings against the directorate for having illegally appointed a new staff contrary to the constitution of the institute.

Personal.—Dr. Samuel M. Henry has been elected mayor of Harrison, Ont.——Dr. James G. Scott, Seaforth, Ont., narrowly escaped death, May 17, when a locomotive struck a hind wheel of his buggy. He was hurrying to cross the track in front of the train.——Drs. Edward O. Steeves, Moncton, Francis J. Desmond, Newcastle, and F. S. Walker, St. John, have been reappointed members of the Board of Health of New Brunswick.——Dr. Walter H. Delaney, M.P.P., Quebec, has returned from Italy.——The physicians of Peterborough County, Ont., gave a dinner in Peterborough, May 14, in honor of Dr. Samuel Payne Ford, Norwood, in celebration of the semicentennial of Dr. Ford's entry into practice. Dr. James T. I. Halliday officiated as toastmaster.——Dr. Arthur W. Moody, Winnipeg, has been appointed chief surgeon of the Manitoba division of the Northern Pacific Railroad, vice Dr. Robert J. Blanchard, resigned.——Dr. Louis de L. Harwood, medical supervisor of the Notre Dame Hospital, Montreal, who was operated on in Paris recently, is reported to be convalescent.

CANAL ZONE

Removal of Tuberculosis Wards.—The tuberculosis and isolation wards on the Ancon Hospital reservation have been removed to La Boca and converted into dwellings. The residence of the governor of the zone will be located on the site of the tuberculosis wards. The isolation wards will be reerected on the site of the hospital garden.

Precautions against Plague.—During April the health officer of the Zone condemned 129 small one and two-story structures in Panama on account of their dilapidated condition and the opportunity afforded by them for harboring rats in the walls and under the floors. The building regulations of Panama require single walls and floors of cement or wood laid on cement. War on rats is being conducted daily and they are examined for plague. The presence of plague at Mantua, Ecuador, forty-eight hours from Panama, makes these operations important.

Quarantine Against Plague at Panama.—On May 20 the government authorities at Panama declared a seven-day quarantine against Colombia on account of bubonic plague which had appeared at several points in that republic. The exact extent of the outbreak is unknown. In connection with this report the comment has been made that the canal will have a great and wide influence on sanitation in countries not now giving sufficient attention to sanitary matters. The prohibition of the use of the canal by shipping from infected ports will induce the government of these countries to clean up.

LONDON LETTER

London, May 15, 1914.

The Clinical Congress of the Surgeons of North America

The program of the congress, which will take place in London from July 27 to August 1, is now completed. During each day members of the congress will be the guests of various hospitals and clinics, and will attend operations and demonstrations by well-known surgeons. The General Surgical Division will hold its meetings in the grand hall of the Hotel Cecil, and the Division of Surgical Specialties in the ballroom of the Savoy Hotel. The American surgeons will be welcomed by Mr. Page, American Ambassador. Dr. John B. Murphy will preside over the congress.

GENERAL SURGICAL DIVISION, GRAND HALL, HOTEL CECIL

Monday, July 27: Address of welcome by Sir R. J. Godlee, president of the Royal College of Surgeons; welcome to American surgeons by the American Ambassador, Mr. Page; address to retiring president, Dr. G. E. Brewer. Inauguration of the president, Dr. J. B. Murphy, and the vice-president, Dr. G. E. Armstrong. "The Choice of the Operative Method for Ulcer of the Stomach," A. von Eiselsberg, Vienna; discussion by Sir Watson Cheyne. Presidential address, "Arthrodesis and Bone Transplantation: Its Limitations and Technic," Dr. J. B. Murphy, Chicago.

Tuesday, July 28: "Cure of Hernia by Tissue Inlaying or Fascial Implantation," Dr. E. W. Andrews, Chicago; discussion by Mr. Lawrie McGavin. "Certain Derangements of the Knee-Joint and Their Treatment," Mr. R. Jones, Liverpool.

Wednesday, July 29: "Typhoid Perforation," Dr. G. E. Armstrong, Montreal; discussion by Sir Anthony Bowlby. "Transplantation of Ovaries," Professor Tuffier, Paris. "Primary and Late Results of Operations for Exophthalmic Goiter or Hyperthyroidism," Dr. Charles H. Mayo, Rochester, Minn.; discussion by Mr. James Berry.

Thursday, July 30: "The Principles of Non-Operative Treatment of Carcinoma," Dr. Krönig, Freiburg. "The Treatment of Inoperable Carcinoma of the Uterus by the Application of Heat," Dr. J. F. Percy, Illinois. "Radical Operative Treatment of Cancer of the Uterus," Mr. T. Wilson, Birmingham; discussion by Dr. T. Watts Eden, Mr. W. E. Miles, London, and Dr. J. C. Bloodgood, Baltimore.

Friday, July 31: "The Use of the Levator Ani Muscle and the Uterosacral Ligament in Prolapse Treatment," Dr. Henry Jellett, Dublin; discussion by Dr. Herbert Spencer. "Surgery of Intestinal Stasis," Dr. J. C. Bloodgood. "Intestinal Stasis," Sir W. Osler, Oxford; discussion by Sir Arbuthnot Lane.

SURGICAL SPECIALTIES, BALLROOM, SAVOY HOTEL

Tuesday, July 28: "The Results of Operations (Laryngofissure) for Cancer of the Larynx," E. Schmiegelow, Copenhagen; discussion by Sir St. Clair Thomson. "The Intranasal Surgery of the Lacrimal Apparatus, after an Experience with over 255 Operations," Dr. J. M. West, Berlin; discussion by Dr. D. R. Paterson, Cardiff.

Wednesday, July 29: "The Applicati [illegible] Mastoid Region and Its Use in the [illegible] Dr. A. Logan Turner, Edinburgh; dis [illegible] Scott. "Some Considerations Which [illegible] of an Operation in Septic Invasion of the Lateral Sinus," Mr. Hugh E. Jones, Liverpool; discussion by Mr. Hunter Tod.

Friday, July 31: "The Sclerocorneal Trephining Operation for Glaucoma," Lieut.-Col. R. H. Elliott, I. M. S., Madras: discussion by Mr. Treacher Collins. "Operative Procedure for Strabismus," Mr. F. Richardson Cross, Bristol; discussion by Mr. N. Bishop Harman. "Operation for Senile Cataract," Mr. J. B. Story, Dublin; discussion by Mr. Holmes Spicer.

The Membership of the British Medical Association

As explained in previous letters, a large accretion took place to the British Medical Association when the profession considered itself threatened by the national insurance act. In the year 1912 the number of new members was 2,500, producing an increase of membership of 1,267. At the end of the year the crisis came and the association attempted to prevent the working of the act, but failed. The profession was divided into two camps, "panel" and "antipanel," and as the latter formed the great majority of the members, the former considered that their interests could not be properly safeguarded by the association. This led to defection which was increased by raising the annual subscription from $6 to $8.50. The result was shown by the resignation of 2,675 members in 1913, causing a decrease of 2,192 in the membership of the association. In Ireland, where the conditions are peculiar, and medical benefit under the insurance act does not exist, the raising of the subscription was especially resented and the membership fell from about 1,000 to 756. It has also been felt that the association has not been of as much political use to Irish members, as its working has been adapted almost entirely to the very different conditions existing in England. An attempt has now been made to retrieve the position by establishing a separate office in Ireland with a whole-time medical secretary. As, however, an Irish Medical Association with a subscription of only $5 a year already exists for the same political purpose, it is very doubtful whether the Association will benefit either itself or the Irish profession by this new departure.

PARIS LETTER

Paris, May 8, 1914.

Personal

At its session, May 5, the Académie de médecine elected Dr. Routier, surgeon to the Necker Hospital, a member in the section of operative medicine, to fill the place left vacant by the lamented death of Dr. Lucas-Championnière. Dr. Routier is known especially for his numerous works on abdominal surgery and gynecology. It was he who in 1890 performed the first interval operation for appendicitis in France.

A Sanitary League against Rats and Flies

A *Ligue sanitaire française contre la mouche et le rat* has just been formed. It purposes the extermination, not only of flies and rats, but also of all disease-carrying vermin, and will institute a propaganda of education in hygiene and sanitation.

The Fight Against Alcoholism in Morocco

Since alcoholism has already begun its ravages in Morocco, the government of the protectorate has deemed it necessary, following the example of the Ivory Coast, to pursue the only really efficacious method: the absolute interdiction of absinthe to Europeans as well as to natives. A decree of the sultan has just been issued which formally prohibits the importation, manufacture, circulation, sale, or detention with a view to selling, of absinthe and similar products in the French portion of the country. Absinthe and similar products may not be made or sold except by pharmacists, under the classification of medicinal products. Every infraction of this decree is to be punished by a fine of from 300 to 3,000 francs ($60 to $600). For a repeated offense, the penalty is imprisonment for from three months to three years. Moreover, any public house in which the sale of absinthe and similar alcoholics is permitted will be closed for six months, aside from the penalty imposed on the proprietor. In case the offense is repeated, the establishment will be closed permanently.

BERLIN LETTER

Berlin, May 9, 1914.

Volunteer School Nurses for Berlin

In Berlin, as elsewhere, advice given to parents by school physicians is not always followed through carelessness, want of judgment or poverty. In many places school nurses have been instituted who take care that the orders of school physicians are followed. As Berlin has not yet installed school nurses, the Berlin Society for Domestic Sanitation will, by order of the city school deputation, establish a school-nurse service, at first in three school physicians' districts. This society has nine district committees in various parts of the city, which through many years' experience in detailed philanthropic work, are familiar with the conditions of the needy residents of their districts and can rely on trained volunteer assistance.

Annual Meeting of German Internists

At the *Kongress für innere Medizin,* which took place from April 21 to 23 at Wiesbaden under the presidency of the Munich clinician, Professor von Romberg, two topics excited the greatest interest, namely, the address of von Behring on his diphtheria prophylactic and the report by Werner of Heidelberg on radiotherapy of neoplasms of the internal organs.

BEHRING'S METHOD OF PROPHYLAXIS OF DIPHTHERIA

At the meeting last year, Behring announced his new prophylactic, which consists of a mixture of diphtheria toxin and antitoxin. From two to three thousand persons have been given the prophylactic, but exact painstaking observations have been made only on about one thousand. To Behring it seems a quite justifiable expectation that by regular and exact use of the T.-A. method, diphtheria may be made an exotic disease just as small-pox has become since the time of Jenner wherever vaccination has been carried out systematically and under the direction of expert physicians. To be sure, Behring admits that the scientific basis and the practical application do not as yet furnish sufficient guarantees for the fulfilment of this hope to its full extent in his lifetime.

In none of the single injections, which number about 7,000, has any harm been done. This results chiefly from the animal experimentation by which Behring secures positive evidence, first, that the preparation intended for the treatment of human beings contains not even a trace of the paralyzing element of the toxin, second, that the toxic power has been exactly determined by trial on guinea-pigs, and third, that especially in horses the capability of producing antitoxin has been learned to a certain degree of reliability. Further, Behring requires the testing of every new lot by his standard preparation M. M. 1, which has retained its toxic and immunizing properties for fifteen months unchanged.

In his first communication Behring could already report that in many cases such a dose of his remedy as is intended for the new-born would cause a marked reaction in older persons, especially in children of school age. An explanation of this fact may be found in the assumption of a specific sensitization in consequence of previous introduction of diphtheria bacilli which renders the individuals hypersensitive to the T.-A. For the great majority of cases, this must be regarded as correct, but in addition we have also a non-specific hypersusceptibility. This was in many cases extraordinarily great in tuberculous and scrofulous persons, in whom, in addition to the intense local reaction, an inclination to a painful swelling of the lymph-nodes appeared. Furthermore, among a large number of new-born and older infants, there were found some which reacted positively to as small doses as the schoolchildren among whom a second trial likewise was positive. Such cases deserve marked attention in reference to prophylactic vaccination against diphtheria because in them the positive reaction is not a sign of production of antitoxin in adequate amounts for protection against diphtheria.

For the purpose of a statistical investigation, intended to show the protective action of the new remedy, Behring would like, for the present, to have the lymphatic constitution and other similar conditions regarded as contra-indications for this method of prophylactic vaccination. He would also exclude from this treatment for the present atrophic infants and infants less than 9 months old.

The subcutaneous injection is recommended as the best method of application. There can be no doubt that, in many cases, a single injection produces a sufficient protection. Such persons are, as a rule, those who have been already sensitized by diphtheria bacilli. For the ordinary run of cases, at least two injections should be made. The first injection then plays the part of a sensitizer; sensitization, experience shows, occurs after from ten to fourteen days, which leads to the requirement that the second injection should not be made until after an interval of not less than ten days.

There are several preparations of T.-A.; T.-A. 8 has the lowest toxicity and has an equivalent value to that of the standard preparation M. M. 1, while T.-A. 7 is ten times and T.-A. 6, twenty times as strong in its toxic and immunizing power for man.

ANTITOXIN IN THE BLOOD

Systematic examination of the blood for antitoxin has shown a surprisingly large number of untreated cases in which the blood already contains antitoxin. Antitoxin could be demonstrated in the blood of not less than from 60 to 80 per cent. of the new-born. The children of the ages which furnish the greatest proportion of cases of diphtheria, however, more rarely show a positive reaction. The fear expressed by some that a protective remedy is not indicated in persons who are already under the influence of an imported diphtheria toxin has been finally dissipated by practical experience. Not one of the numerous bacillus-carriers that have been injected with T.-A. have sickened from diphtheria. Whether or not the active immunization with T.-A. will help them to get rid of the diphtheria bacilli is an open question.

VIENNA LETTER

Vienna, May 5, 1914.

The Program of Lectures for the Summer Term

The official program of the lectures for the coming term of the Medical Faculty of Vienna has recently been published. Primarily, the lectures and classes are arranged for the medical students and only a few of them are intended for doctors of medicine. The latter are expected to attend the postgraduate classes, notices of which are published from time to time. On application from a certain number of men (from six to eight) any one of the professors or lecturers will be willing to arrange a special class or course. The students' courses will number 429, lasting between sixteen and fifty hours each. They will comprise the whole field of medicine. Naturally, internal medicine (with ninety-eight different classes) and surgery (with forty-two classes) lead. The prominence of rhinolaryngology and otology is shown by the twenty-two classes on these subjects.. Anatomy, bacteriology and serology are not in such demand. A staff of 114 professors, eighty-five of whom are eminent, together with 133 docents and assistants, will direct the work.

The program contains also some figures as to the number of students in the last (winter) term. At the University of Vienna, from a total of 10,310 students, 3,018 were medical students, of whom 190 were women. The seven other universities of Austria had 31,397 students, of whom 7,330, or 23 per cent., were medical students. There were 320 female medical students, or a little over 4 per cent. of the total; 2,280 students, or 30 per cent., did not speak German.

The German constituent comprises 45 per cent. of the population of this country. It seems, therefore, that the other nations are attempting to make up for the previously wrong national distribution of qualified men. Within the last ten years the total number of medical students has risen from 18 to 30 per cent., and the increase of first-year medical students, against which there was such a bitter complaint, is due chiefly to this fact. It is also gratifying to learn that the number of foreign doctors attending the Vienna University is also increasing. Last term the number rose to 16 per cent.

The Third International Congress for Occupational Diseases

During September an international congress on occupational and industrial diseases will be held in Vienna. It will be associated with an exhibition which will illustrate the development and prevention of diseases caused by certain occupations and the influence of certain occupations on health and hygiene in general. The following subdivisions of the field to be covered have been made and the men named will speak on the subject: 1. "Fatigue," the physiology and pathology of labor on the nervous system, on the bones, static factors and night-work, Professor Durig, Vienna. 2. "Work in Moist and Hot Air," Professor Carozzi, Milan. 3. "Anthrax," Professor Schattenfroh, Vienna. 4. "Pneumoconiosis," Prof. L. Devoto, Milan. 5. "Injuries by Electricity in Industries," Professor Langlois, Paris. 6. "Industrial Poisons," Professor Lehman, Wurzburg. (This will also include the commercial handling of poisons in large quantities.) 7. "Injuries to the Auditory Nerves by Occupations." Several will speak on this subject.

In connection with the congress, excursions will be conducted to the large industrial establishments in which the modern equipments for the prevention of industrial injuries will be studied, including trips to the mines, and paraffin and kerosene wells.

Health of Vienna in the First Quarter of This Year

The official monthly report for March of the Board of Health includes the facts of the two preceding months. Thus, the year 1914 has been extremely favorable in the mortality and morbidity rates from infectious diseases. A marked drop is noted, especially in scarlet fever and diphtheria, while the foggy weather of February has been characterized, contrary to expectation, by constant temperature and low morbidity. The mortality is now below 15 per cent., the yearly average being 16.2 per cent. The infant mortality is still high, causing 21 per cent. of total deaths, while senility causes 3 per cent. of deaths.

Marriages

William Emery Harrington, M.D., Waukita, Okla., to Miss Evelyn Epperson, in Enid, Okla., recently.

Sydney Smith Carrier, M.D., Pittsburgh, Pa., to Miss Lillian Simrall Hunter of Louisville, Ky., May 14.

Edmund W. Meisenhelder, Jr., M.D., to Miss Francis Foust, both of York, Pa., in Harrisburg, May 9.

William Mecklenburg Polk, M.D., to Miss Maria H. Dehon, both of New York City, May 12.

Franklin Herbert Sisler, M.D., to Miss Blanche Virginia Deitrick, both of Sun, W. Va., May 13.

P. A. Surg. Edward Urbane Reed, U. S. N., to Miss Nellie Hall Bayles of Denver, Colo., May 12.

Elijah A. Lambert, M.D., Denton, Ga., to Miss Mary Lawrence of Ashburn, Ga., April 30.

Andre William Reggio, M.D., to Miss Marian Shaw Lovering, both of Boston, recently.

Frank B. Sorgatz, M.D., to Miss Vera Van Winkle, both of Oklahoma City, Okla., May 3.

Waverly Daniel Bretz, M.D., to Miss Vera Canz, both of Memphis, Tenn., May 8.

Deaths

Niles Theodore Quales, M.D. Rush Medical College, 1866; a Fellow of the American Medical Association; and Nestor of the Scandinavian physicians of the Northwest; died at his home in Chicago, May 23, from pneumonia, aged 83. He was born in Hardanger, Norway; had his preliminary education in Norway and Denmark, and in 1859 came to Chicago. On the outbreak of the Civil War, he enlisted; and at its conclusion entered Rush Medical College. He was first intern in the old Cook County Hospital; and during the small-pox epidemic of 1868-1870, he was city physician and director of the small-pox hospital then located near the lake on North Avenue. He was also in charge of the United States Marine Hospital until the Chicago fire of 1871. In 1894 he was made president of the Scandinavian-American Medical Society; and in 1910 was honored by King Haakon of Norway with the Order of Saint Olaf. He was the founder of the Norwegian Old People's Home, Norwood Park; and was always prominent in charitable work among the Scandinavians of the city. At his funeral, May 26, members of the Scandinavian-American Medical Society officiated as pallbearers.

Julia Dyer Merrill, M.D. Northwestern University Women's Medical School, Chicago, 1895; formerly superintendent of nurses in the North Adams, Mass., Training School; and after her graduation in medicine, assistant to Dr. A. C. Cotton, Chicago, for several years; assistant clinical professor of pediatrics in Rush Medical College from 1897 to 1913; and a member of the pediatric staff of Presbyterian, Tabitha, Chicago Maternity, Maimonides and Mary Thompson hospitals; and deeply interested in various orphanages, sanatoriums for babies, and other infant welfare organizations; a member of the Chicago Milk Commission from its inception until 1913; a Fellow of the American Medical Association; died at her home in Chicago, May 17, from infectious endocarditis complicated with pneumonia, aged 53.

Charles Enfield, M.D. College of Physicians and Surgeons in the City of New York, 1870; a Fellow of the American Medical Association and American Academy of Ophthalmology and Laryngology; a member of the American Association for the Advancement of Science, and the American Association of Railway Surgeons; a veteran of the Civil War, in which he served in the Hospital Corps of the First New York Volunteer Infantry; a practitioner of Jefferson, Iowa, since 1871; died at his home in that place, May 7, from pneumonia, aged 71.

Thomas Mackaness Ludlow Chrystie, M.D. Bellevue Hospital Medical College, 1867; a member of the Medical Society of the State of New York; an ensign in the Navy during the Civil War; for many years a practitioner of New York City, and for quarter of a century physician to the New York State Branch of the Order of the Cincinnati; died at his home in Rye, N. Y., May 19, aged 72.

Carl Robert Feld, M.D. Rush Medical College, 1891; a Fellow of the American Medical Association, and secretary of the Jefferson County (Wis.) Medical Society, since its organization; for twenty years clerk of the Board of Education of Watertown, Wis.; a member of the state legislature in 1885, 1887 and 1889; for nearly twenty years health commissioner of Watertown and the township of Lebanon; died at his home in Watertown, May 12, from diabetes, aged 55.

Gustavus Brown Thornton, M.D. New York University, New York City, 1860; a Fellow of the American Medical Association; regimental, brigade and division surgeon in the Confederate service throughout the Civil War; local surgeon of the Memphis Division and Terminal, Illinois Central and *Southern Railway; for many years superintendent of the* Memphis City Hospital, and president of the Board of Health of the city, died May 13, aged 79.

Henry Clay Devilbiss, M.D. College of Physicians, Baltimore, Md., 1877; a Fellow of the American Medical Association; formerly president of the Medical Society of Franklin County, Pa.; treasurer of the Cumberland Valley Medical Association; and since its organization, a member of the medical staff of the Chambersburg Hospital; died at his home in Chambersburg, Pa., May 17, aged 65.

J. K. Robinson, a non-graduate of Randolph County, Mo., who practiced for a year under his preceptor, and then became a clergyman; died at his home in Clark, Mo., March 23, from endocarditis, following influenza, aged 70.

Robert Hughes Hayes, M.D. Washington University Medical School, St. Louis, 1879; a member of the Medical Association of the State of Alabama; died at his home in Union Springs, Ala., May 3, from heart disease, aged 56.

John McCroskery, M.D. Bellevue Hospital Medical College, 1887; a Fellow of the American Medical Association; of New York City; died suddenly from heart disease while making a professional call, May 9; aged 49.

William Francis Gleason, M.D. Harvard Medical School, 1886; a member of the Rhode Island Medical Society; formerly chairman of the school committee of Providence; died at his home in that city, April 29, aged 52.

Philander Palmer (license, Michigan, twenty-four years of practice, 1900) a veteran of the Civil War; one of the oldest practitioners of Grand Haven, Mich.; died at the home of his son in that city, May 4, aged 77.

David Alexander Ryan, M.D. Dearborn Medical College, Chicago, 1906; formerly a member of the staff of the German Hospital; died at his home in Chicago, May 15, from a nervous breakdown, aged 55.

James W. La Force, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1856; a pioneer practitioner of Eldon and Floris, Iowa; died at the home of his daughter in Bloomfield, Iowa, May 4, aged 87.

James F. Keith, M.D. Missouri Medical College, St. Louis, 1871; president of the Citizens' Bank of Sturgeon, Mo.; died in a hospital in St. Louis, about April 30, from disease of the bladder, aged 64.

Hiram O. King, M.D. Detroit Medical College, 1876; a member of the Indiana State Medical Association; died at his home in Kendallville, Ind., May 5, from disease of the spinal cord, aged 62.

Robert King, M.D. New York Homeopathic Medical College, 1863; for thirty years a practitioner of Emporia, Kan.; died at his home in that city, May 2, from malignant disease, aged 74.

Ira Young Kezartee, M.D. University of Michigan, Ann Arbor, 1867; for twenty-two years a practitioner of Battle Creek, Mich.; died at his home in that city, May 4, aged 69.

John Alvin Graham, M.D. Western Pennsylvania Medical College, Pittsburgh, 1890; died at his home in West End, Pittsburgh, May 1, from disease of the stomach, aged 47.

Thomas Harding Ellis, M.D. Medical College of Virginia, Richmond, 1884; formerly of Montebello, Va.; died at his home in Glenwood, N. C., March 25, aged 51.

Alonzo N. Sheffner, M.D. Bennett Medical College, Chicago, 1873; a veteran of the Civil War; died at his home in Hay Springs, Neb., April 30, aged 73.

Mary C. Farnham, M.D. Hahnemann Medical College, Chicago, 1881; died at her home in Denver, Colo., May 2 from pleuropneumonia, aged 71.

Phillip Heldrich, M.D. University of Maryland, Baltimore, 1883; formerly of Elmira, N. Y.; died at his home in Baltimore, May 1.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

LIQUID PETROLATUM OR "RUSSIAN MINERAL OIL"

Report of the Council on Pharmacy and Chemistry

The following report was submitted to the Council by a referee and its publication authorized by the Council.

W. A. Puckner, Secretary.

Petroleum has been in use as a medicine from time immemorial. It was known to Herodotus 400 years before Christ and is mentioned by Plutarch, Dioscorides, Pliny and other early writers. It was extensively used by the Arabians and evidently played an important part in the practice of medicine in India, being known to the Bengalese as Muthe Katel. The raw product was the substance used in earlier times and differed much in character and composition, as obtained from different sources.

As an internal remedy it was early employed in chronic pulmonary affections, in obstinate skin diseases, in rheumatism, and for the expelling of tapeworms. It was extensively used for these several purposes in France under the name of "Oleum Gabianum" and in North America as "Seneka oil."

The internal use of the refined product may be traced to a patent granted to Robert A. Chesebrough of New York, in June, 1872, for the manufacture of a "new and useful product from petroleum, named vaseline." This name was originally applied only to a semisolid preparation, but later a liquid product known as liquid vaseline was marketed and for a time exploited as a cure for coughs, colds, consumption and a number of other diseases and conditions.

The liquid petrolatum has since become known under a variety of names, proprietary and otherwise, in addition to being used as a substitute or an adulterant for other, more costly, fats and oils. Some of the names applied to the product are:

Adepsine oil
Amilee
Atoleine
Atolin
Blandine
Crysmalin
Deeline
Glyco
Glycoline
Glymol
Heavy petroleum oil
Liquid Albolene
Liquid Cosmoline
Liquid Fossiline
Liquid Geoline
Liquid Paraffin
Liquid Petrolatum
Liquid Saxoline
Liquid Vaseline
Mineral Glycerin
Mineral Oil
Neutralol
Olo
Paraffin Oil
Paroline
Petralol
Petro
Petrolax
Petrolia
Petronol
Petrosio
Rock Oil
Russian liquid petrolatum
Russian mineral oil
Russian paraffin oil
Russol
Saxol
Terraline
Terralbolia
Usoline
Water-white mineral oil
White paraffin oil.

A preparation similar to that official in the Pharmacopeia of the United States as liquid petrolatum has been included in many, if not all, of the foreign pharmacopeias, the official titles under which this preparation is recognized being as follows:

Petrolatum Liquidum, U. S. Pharmacopeia; Paraffinum Liquidum, pharmacopeias of Great Britain, Germany, the Netherlands, Japan, Belgium, Austria, Denmark, Switzerland, Sweden, Servia, Italy, Hungary and Russia; Oleum Paraffinae, Spanish Pharmacopeia; Vaselinum Liquidum, French Pharmacopeia, and Oleum Vaselini (as a synonym) pharmacopeias of Denmark and Russia.

The requirements of the several pharmacopeias differ somewhat and the specific gravity as given is as follows:

U. S. P. VIII, 1905	0.870	to	0.940	at 25°
Ph. Brit. IV, 1895	0.885	to	0.890	at 15.5°
B. P. C. II, 1911, usually	0.875	or	lower	at 15°
Ph. Germ. V, 1910, at least	0.885			at 15°
Ph. Ross. VI, 1910	0.880	to	0.885	at 15°
Ph. Hung. III, 1909	0.88	to	0.89	at 15°
Ph. Ital. III, 1909	0.875	to	0.890	at 15°
Ph. Fr. V, 1908, about	0.875			at 15°
Ph. Serb. II, 1908, about	0.880			at 15°
Ph. Svec. IX, 1908	0.88	to	0.90	at 15°
Ph. Helv. IV, 1907	0.880	to	0.885	at 15°
Ph. Dan. VII, 1907, at least	0.880			at 15°
Ph. Austr. VIII, 1906, at least	0.880			at 15°
Ph. Belg. III, 1906, not below	0.880			at 15°
Ph. Japon. III, 1906	0.875	to	0.945	at 15°
Ph. Ndl. IV, 1905, not below	0.860			at 15°
Ph. Hisp. VII, 1905	0.840			at 15°

For pharmaceutical purposes, liquid petrolatum may be divided into two grades, the lighter or more limpid oil, used extensively as a vehicle for oil sprays, and the heavier, more viscid oil generally recognized in European pharmacopeias and used as an ingredient of ointments and more recently as a remedy in the treatment of intestinal stasis.

Under petrolatum liquidum the U. S. P. recognizes a mixture of hydrocarbons, chiefly of the methane series, which occurs as a colorless or very slightly yellowish, oily, transparent liquid without odor or taste and having a specific gravity of about 0.870 to 0.940 at 25 C. For the U. S. P. IX, it is proposed to change this requirement somewhat so as to have it apply to a transparent liquid free from fluorescence, without odor or taste and having a specific gravity of from 0.845 to 0.940 at 25 C.

Such a requirement would include all of the available paraffin oils irrespective of origin. The now commonly available commercial liquid petrolatum, used for pharmaceutical purposes, is practically colorless and all of the better grades are free from odor or taste. The specific gravity varies from 0.855 to 0.895. The lighter oils, having a specific gravity of from 0.860 to 0.870, are usually preferred in the making of oil sprays or solutions of substances to be used as local applications. The product having a specific gravity above 0.875 evidently contains a considerable amount of dissolved solid paraffin which separates out at temperatures at or below 0 C., but readily dissolves again at temperatures above 10 C.

There is considerable difference in the chemical composition of the paraffin oils obtained from various sources. The American oil consists largely of hydrocarbons of the methane series, while the Russian oil contains naphthenes or hydrocarbons of the benzene series, having the empirical composition of ethylene, (C_nH_{2n}) which may be considered as hydrogenated aromatic hydrocarbons, though they behave with reagents very much in the same way as do the hydrocarbons of the methane series.

Mineral oils with a naphthene base are best suited for making white petrolatum, and at the present time the production of the colorless water-white liquid petrolatum appears to be confined largely or almost exclusively to the crude product of the Baku district of Russia, though it is asserted that it is now also made from the Hanover (Germany) crude oil and that some is being produced by "cracking" the white solid paraffin.

It is also said that the American oil can be made water white but that it is not being so produced at present for economic reasons; the yellowish oil, free from fluorescence, having a very wide sale, both as a lubricant and as a substitute for lard oil and other of the more costly lubricating oils.

From a pharmaceutical point of view it would appear important to note the physical characteristics of the oil and to insist on absence of color, absence of odor and taste, absence of acid and of alkali and a specific gravity in harmony with the purposes for which the oil is to be used.

During the past year or two liquid petrolatum has attracted considerable attention as a remedy in the treatment of intestinal stasis or chronic constipation, the practice of using it having been developed largely through its recommendation by Sir W. Arbuthnot Lane and his associates. This use of liquid petrolatum and of petrolatum products generally is by no means novel. N. A. Randolph[1] of Philadelphia, was among the first to suggest its use for this purpose in an article published in 1885. Randolph also appears to have been the first to experiment with petrolatum and to determine its non-absorbability from the intestinal tract. In an article[2] in 1884 he concludes that "pure petrolatum while entirely unirritating to the digestive tract is valueless as a *foodstuff*."

The experiments recorded by Randolph were evidently prompted by the fact that vaseline and a number of imitation products then on the market were being sold as substitutes for lard and butter, and opinions regarding the food value of petroleum products appear to have differed very materially. Following the experiments of Randolph, Robert Hutchison in 1899 made a series of experiments to demonstrate that petroleum, petrolatum, paraffin and related products were absolutely unassailable by any of the digestive fluids, despite the "large vogue that had of late years been given to various petroleum emulsions, chiefly by ingenious and unterrified advertising." He came to practically the same conclusions arrived at by Randolph fifteen years earlier and pointed out that "liquid paraffin in one sense may be regarded as an artificial intestinal mucus and might in that way have some value on certain forms of constipation."

William Duffield Robinson[3] reports on the use of a perfectly refined colorless and odorless petrolatum, supposedly of American origin. He was able to show that all of the product passed unchanged through the intestinal tract and could be regained from the feces. In his conclusions he expressed the belief that the effect of the administration of these petroleum products is far more than as a simple intestinal lubricant. In over fifty selected cases in which nutrition, digestion and body-weight were impaired, and the purest oil administered in 1- or 2-dram doses each day for a period of from four to six months, there was in every instance an improvement of weight, health and feeling of well-being. The administration of refined paraffin oil gave no discomfort in any instance, even in cases in which nearly a pint was given in a few hours.

William Ewart[4] suggests liquid paraffin as a safe agent for the local treatment of the lesions in typhoid fever. He says in part: "Mineral oil, such as petrolatum or paraffin, is neither absorbed nor dissolved; therefore, after all absorbable ingestions are taken up by the lacteals, it will still remain in the bowel. In this way pure liquid paraffin is valuable, precisely because it is inert; moreover, it might some day, perhaps, be made the vehicle for effective topical remedies."

A. D. Schmidt[5] quotes Stubenrath as having given liquid paraffin in the treatment of chronic constipation, and he himself gave as much as 20 gm. of liquid paraffin to adults without observing any injurious effect whatever. He says, "As a result of the administration of liquid paraffin, the feces are softened considerably and are found under the microscope to contain numerous minute globules of paraffin." He was, however, unable to recover from the feces the entire quantity of paraffin administered and believes that a certain portion of it, probably the fractions with a low boiling-point, are absorbed or possibly oxidized in the organism.

Maurice Vejux Tyrode[6] also refers to the use of liquid petroleum in the treatment of constipation.

Sir W. Arbuthnot Lane in his recommendations of liquid petrolatum calls it an ideal remedy for stasis, but cautions against the use of the lighter oil as extensively prescribed in this country as a vehicle for sprays in nose and throat work.

Paraffin oil is not absorbed from the alimentary tract and so far as known exerts no deleterious influence. It is usually given in quantities of from 10 to 20 c.c. half an hour or an hour before meals or in larger doses, from 30 to 50 c.c., at one time on retiring. From available evidence it appears that comparatively huge doses may be administered without the production of any untoward results. According to many observers, liquid paraffin should not be given with or after meals because of the inhibiting influence that it may have on the digestion of food. It is not soluble in water or the ordinary solvents and therefore cannot be diluted. The denser oils are preferably slightly warmed or drunk with warm water so as to obviate the disagreeable slimy sensation that persists when taken cold.

Volatile oils may be used in moderate amounts to give a distinctive taste to the otherwise rather insipidly tasteless paraffin oil. Among the more desirable oils to be used for this purpose would be oil of peppermint, oil of cinnamon, oil of betula or methyl salicylate and oil of cloves. From 2 to 10 drops of any of these oils can be added to a pint of the oil. When larger doses of the oil are to be given at one time, it would, of course, be advisable to use a comparatively smaller quantity of the volatile oil as a flavor.[7]

From the foregoing it would appear that apart from the Pharmacopeia of the United States, practically all other known pharmacopeias describe a water-white mineral oil under the title "Paraffinum Liquidum" or "Liquid Paraffin" as a colorless, odorless, tasteless, non-fluorescent, oily liquid, free from acids, alkalies and organic impurities. As explained before, the specific gravity of the preparation as recognized in other countries and as offered on the American market at the present time varies considerably, and there appears to be some difference of opinion as to the exact nature of the product that is preferable for use for different purposes. This matter requires further investigation.

Since the definition of liquid petrolatum in the U. S. Pharmacopeia permits the use of fluorescent products of widely varying specific gravities, it is recommended that physicians who desire the water-white non-fluorescent (Russian) mineral oil should use the term "Petrolatum Liquidum, Grave," or "Paraffinum Liquidum, B. P.," if the heavy product recommended by Lane is desired, and "Petrolatum Liquidum, Leve" if the light varieties are required. It is further recommended that under the foregoing names, manufacturers and pharmacists be requested to dispense the products, in accordance with the following descriptions:

Petrolatum Liquidum, Grave.—Heavy (Russian) Liquid *Petrolatum.—Paraffinum Liquidum, B. P., liquid paraffin.*—A transparent, colorless, tasteless, non-fluorescent, oily liquid, odorless when cold but giving off a faint petroleum odor on heating. This preparation should correspond to the requirements of the British Pharmacopeia for liquid paraffin and have a specific gravity of about 0.885 to 0.890 at 15 C. It is insoluble in water or alcohol but soluble in boiling absolute alcohol and readily soluble in ether, chloroform, carbon disulphide, petroleum benzin, benzene and fixed and volatile oils. It serves as a solvent for volatile oils and related substances like camphor, menthol and thymol.

This is the type of preparation used by Sir W. Arbuthnot Lane, and his associates for internal administration. It is also used as a basis for ointments and salves and as a local application to wounds, ulcers and in certain forms of skin diseases in which a simple protective is desired.

Petrolatum Liquidum, Leve.—Light (Russian)—Liquid Petrolatum.—A transparent, colorless, tasteless, non-fluorescent, oily liquid, odorless when cold, but giving off a faint petroleum odor on heating. In other respects this preparation should correspond to the pharmacopeial tests for liquid petrolatum and have a specific gravity of about 0.860 to 0.875 at 15 C. Like the heavy variety of liquid petrolatum, it is insoluble in water and alcohol, but soluble in boiling absolute alcohol and readily soluble in ether, chloroform, carbon disulphide, petroleum benzin, benzene and fixed and volatile oils. It serves as a solvent for volatile oils and related substances like camphor, menthol and thymol.

This is a type of preparation extensively used as a vehicle for the oily sprays in nose and throat work. It is also being used as one of the constituents in the now popular paraffin oil cold cream and has been used to some extent for internal administration in the treatment of chronic stasis. Being more limpid than the preparation preferred by Lane, it is more readily taken, though greater care must be exercised in securing a sample devoid of the lighter fractions of petroleum distillates.

GERALD MACAURA—INTERNATIONAL QUACK

An American Impostor who Defrauded the British with Impunity but was Unappreciated by the Germans and French

Gerald Macaura is a quack of international notoriety who calls himself "doctor" and claims to be a graduate of the National Medical University of Chicago. The official list of the alumni of the National Medical University of Chicago does not contain Macaura's name. Even if it did, Macaura would have nothing to brag about, for the National Medical University, now defunct, was an institution of the sun-down variety whose reputation was so unsavory that it was not recognized by the authorities of the very state in which it did business.

Gerald Macaura calls himself a "vibrotherapist." In 1904 he was in Baltimore. About a year later he transferred his activities to Dublin, Ireland, where in partnership with another quack, one Dick Sorelle, he conducted a medical institute under the title the "American Doctors." Like other quacks—medical and otherwise—he commercialized his country's emblem by floating the Stars and Stripes above his fakery. In those days, it seems, Macaura had not started his vibrotherapy fraud, but was relieving the gullible of their money *via* the "electric treatment" route.

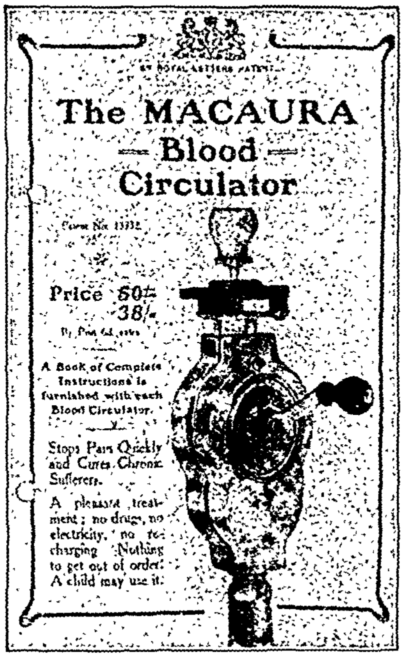
W. T. STEAD TO TEST MACAURA'S PULSOCON.

STEAD AND HIS PATIENTS AT CLAVIER HALL.

Greatly reduced reproduction of some of the advertisements run by Macaura in the London newspapers during his campaign in that city. Note the way in which the late editor of the English *Review of Reviews* was made an advertising asset by this quack. Macaura opened his advertising campaign by hiring the Royal Albert Hall, later he used *Clavier Hall.*

In 1908 Macaura crossed the Irish channel and opened another "institute" in Manchester, England. It was at this time that he brought out his "blood circulator" which, he assured his dupes, was "Protected by His Majesty's Royal Letter Patent." The "blood circulator" he first christened the "Pulsator," but later changed its name to the "Pulsocon." Finding the English so naively gullible Macaura soon decided that Manchester offered too small a field for his talents, and in 1910 went to London. It was here that he gave full play to his advertising genius—for the swindler undoubtedly has genius in this line. He rented the Albert Hall, one of the largest auditoriums in London, and opened his campaign with a two-night "show" that was widely advertised in the London newspapers. Macaura spent tens of thousands of pounds on newspaper advertisements.



BY ROYAL LETTERS PATENT.

The MACAURA
Blood
Circulator

Patent No. 13332

Price 60/-
38/-
By Post 6d. extra

A Book of Complete Instructions is furnished with each Blood Circulator.

Stops Pain Quickly and Cures Chronic Sufferers.

A pleasant treatment; no drugs, no electricity, no recharging. Nothing to get out of order. A child may use it.

Photographic reproduction of the back cover of Macaura's booklet showing the vibration device sold in England under the name "Pulsocon" and in the United States as the "Cirkulon."

As a master-stroke of advertising, Macaura was able to interest the late W. T. Stead in his faking and page after page of the London papers were filled with Macaura's blatant advertisements in which Stead's name was capitalized and used as a huge advertising asset. Mr. Stead was undoubtedly honest in his belief that Macaura had something of value in his widely heralded treatment. In this instance, as in some others equally well known, the late editor of the English *Review of Reviews* showed a sincerity of purpose that was exceeded only by his appalling lack of judgment on things medical. A few years before, Mr. Stead had advocated the notorious Count Mattei "cancer cure" which investigation showed to consist of nothing but water; later, he came to the support of an equally worthless cure for cancer—violet leaves; then it was Macaura's "Pulsocon." Needless to say, Macaura took full advantage of the publicity given him by his champion, Mr. Stead, and he reaped a golden harvest. Needless to say, too, when Mr. Stead finally admitted the worthlessness of Macaura's "treatment" the publicity given this admission was practically *nil.*

How beautifully Macaura worked the British public can be gathered from the following incident. One of the cheaper evening London papers in the summer of 1910 contained this news item:

> WELL-KNOWN DOCTOR'S CHAUFFEUR FINED
>
> At Beaconsfield Police Court yesterday the chauffeur employed by Dr. Gerald Macaura, inventor of the Macaura machine, was fined £5 and £3 8s 6d costs for exceeding the speed limit.
>
> Dr. Macaura explained that he was behind with his appointments with several important patients, and was at the time on his way to the residence of the Earl and Countess Roberts at Ascot.

Eight guineas and six pence is certainly dirt cheap for such a magnificent puff. What plebeian cockney, with "a sneaking liking for a lord," could withstand the subtle suggestion that by purchasing one of Macaura's "Pulsocons" he would be able to obtain the same "treatment" as that given to Earl Roberts?

In time, as in all such cases, the British realized what Macaura was, and his blatant and mendacious advertising was insufficient to overcome the counter-force of the knowledge of his inefficiency and fraud. Then in the autumn of 1911 the quack announced that he was coming back to the United States. At the time, THE JOURNAL[1] felicitated London on being well-rid of a most undesirable citizen. For some reason Macaura changed his mind and instead of returning to the United States transferred his fraudulent operations to the continent. In Germany he found a paternalistic government that interfered with his swindle, and in the latter months of 1912 the newspapers announced that Macaura was expelled from Prussian State Territory on the charge of "attempt to cheat." In Paris he fared even worse, although he found several Parisian papers that were willing to share in the fraud money he obtained from the sick. The public prosecutor accused Macaura of illegal practice of medicine and the quack was arrested on the charge of swindling. The case was decided a few days ago when, according to the Associated Press reports, Gerald Macaura was sentenced to three years' imprisonment and a fine of $600 on a charge of fraud.

AILY MIRROR Page 15

DR. MACAURA, F.R.S.A.,

Late member of the Royal Institute of Public Health, London, and graduate of the National Medical University of Chicago. Dr. Macaura successfully demonstrated on Thursday and Friday on test patients submitted by Mr. Stead at Clavier Hall to huge and fashionable audiences. The treatments, it is understood, were entirely satisfactory to Mr. Stead and his physicians

One of Macaura's advertisements appearing in the London *Daily Mirror*. Notice his claim to have been graduated by the National Medical University of Chicago. The official list of the alumni of the National Medical University does not give Macaura's name. If it did Macaura would have nothing to be proud of as this "university" was a night school not recognized by the Illinois authorities.

After Macaura has served "time" he will probably return to the United States, where he may feel tolerably safe in conducting his quackish operations, provided he does not come in conflict with the federal laws. In fact, the device by which he has swindled so many thousands, has come to the United States ahead of its self-styled inventor. In this country it is not sold as the "Pulsocon" but as the "Cirkulon." The "Cirkulon" is exploited by the Cirkulon Institute, 1109 Grand Avenue, Kansas City, Mo. In Great Britain Macaura's device sold for 38 shillings (about $9.50). When purchased in Kansas City, however, $15 is the price. At present the "Cirkulon" is not being pushed extensively. We may expect three years hence, when its "inventor" is able to put aside his convict's suit and again don civilian garb that an energetic campaign will be started. So long as gullibility remains rampant—so long will swindlers of the Macaura type flourish.

Association News

"MEMBERSHIP" AND "FELLOWSHIP" DEFINED

Members Must Qualify as Fellows to Participate in Scientific Assembly at Annual Session

In order that the distinction between membership and Fellowship in the Association shall be fully understood, attention is called to the following excerpts from the By-Laws:

> MEMBERS.—The members in good standing of the constituent state and territorial medical associations of the American Medical Association shall be members (Sec. 1, Chap. VIII).
>
> FELLOWS, ASSOCIATE FELLOWS, HONORARY FELLOWS.—Any member of this Association, who on the prescribed form shall apply for Fellowship and subscribe for THE JOURNAL, paying the annual dues for the current year, shall be a Fellow.
>
> Commissioned medical officers of the United States Army, United States Navy and the United States Public Health Service shall be Fellows of this Association so long as they are engaged actively in their respective service, and thereafter if they have been retired on account of age or physical disability. These Fellows shall not be required to pay dues and shall not receive THE JOURNAL of the American Medical Association except by personal subscription.
>
> There shall be associate and honorary Fellows who shall be elected and shall qualify in accordance with the provisions set forth in these By-Laws.
>
> Members, associate members and honorary members of this Association at the time of the adoption of this By-Law shall be respectively Fellows, associate Fellows and honorary Fellows; and in interpreting these By-Laws, "membership" in the Association at the time of the adoption of this By-Law shall be construed as Fellowship (Sec. 4, Chap. VIII).

As is clearly indicated, the relationship of the individual to the organization is in no wise changed from what it was prior to the 1913 session. The only change is that those who were formerly called "members" are now termed "Fellows." As indicated in the following quotation from the By-Laws, Fellows, in contradistinction to those now holding membership only, are entitled to register at the annual session of the Association:

> None but Fellows, associate Fellows, honorary Fellows and invited guests shall be allowed to register or take part in the scientific meetings of the Association.
>
> No Fellow shall be eligible to register at an annual session until he has paid all of his current indebtedness.
>
> No Fellow shall take part in the proceedings of the Association, or of any of the sections, until he has registered his name and address in the registration office (Chap. IX).

Correspondence

How the Eugenic Marriage-Law Works Out

To the Editor:—A great deal has been written on this much-mooted question, but this is probably the first report of the practical working out of the law in two specific cases—specific, both in the practical working out of the law, and specific pathologically and I might say psychopathically.

CASE 1.—A man about 36 years of age came to me, April 17, and told me he was about to be married and wanted me to examine him and sign his marriage certificate.

On my refusal to sign his certificate without his having taken a Wassermann test, he went to one of a group of physicians connected with a certain maternity hospital, who had sent out word to the public through the press that they would sign marriage certificates without the applicant having to take a Wassermann test. Anyway, one of these physicians signed his certificate, evidently without much energy wasted in a physical examination, and took his three dollars, which is the fee established by the eugenic law. I say "without much energy wasted in a physical examination," because while he was at my office I discovered on a cursory examination a distinct suspicious specific scar. His voice was also suspicious, being husky and guttural. After obtaining the marriage certificate as above stated, he came back to me for advice. I advised him to have a Wassermann taken, and he went to Dr. Hopkinson's laboratory, and the doctor reported to me that it was distinctly positive. When I told him that he had syphilis and should not get married until at least two years from now, he said that he could not help it now, as everything was arranged for the wedding, and asked me what was the next best thing to do. On my advice, he took an intravenous injection of neosalvarsan the day before he was married, which was Friday, April 24. Now, his having syphilis, according to this much-boasted law, should have prevented the marriage ceremony, and my only object in reporting this case is to show that there are physicians in Milwaukee and probably elsewhere in the state who think that they are getting easy money by putting their names to these slips, which is, without doubt, perjury, in some instances.

---

[1] "Macaura Comes Back," editorial, THE JOURNAL A. M. A., Aug. 5, 1911, p. 485.

Case 2.—This is another example of the manner in which this much-boasted law worked out. While this case has not come directly under my observation, it has appeared in the public press, and is known to all. A woman has been posing and masquerading as a man in Milwaukee for the past ten years. She has held numerous positions of a masculine character, from bell-hop to bookkeeper. She recently developed an unnatural affection of a psychopathic type for another girl, and wanted to marry her. In order to carry out the rulings of the eugenic law, she had to get a certificate that "he" was free from all venereal diseases, from a physician. She went to a physician, who, by the way, is a member of our county and state medical societies, and he signed her certificate, thinking all the time that she was a man.

What kind of an examination could have been made? It is stated in the press that the doctor made a blood examination, but we rarely, or never look for the gonococcus of Neisser in the blood. Both physicians referred to in the above report are members of the Milwaukee County Medical Society.

The certificates provided by the Wisconsin Eugenic Law, read as follows:

> I, ——————————being a legally licensed physician, do certify that I have this ——— day of ————————, 19——, carefully and thoroughly examined————————————, having applied the recognized clinical and laboratory tests of scientific search and find him to be free from all venereal diseases, so nearly as can be determined.

The word "search" in the certificate I have never heard accounted for, but we know that it probably means "research."

Section 7 of the Wisconsin Eugenic law reads as follows.

> Any physician who shall knowingly or willingly make any false statement, in the certificate provided for in Subsection 1, of this section, shall be guilty of perjury, and a conviction under this subsection shall revoke the license of such physician to practice in this state.

What is to stop some innocent victim, a wife, for instance, from bringing suit for damages against the physician for signing a marriage certificate without complying with the law, if she should develop syphilis or gonorrhea from her newly married husband? All she will need is the proof, which can easily be obtained if these physicians continue to take "easy money" without proper and necessary examination. In the name of common decency, if we are to have such a law, let us uphold it, and not make ourselves the laughing-stock of the public.

The following comment from the Milwaukee *Free Press* shows the layman's attitude on the subject:

> The eighteenth century, in spite of its boasted "reign of reason," was gullible to a degree. Theophile Gautier stands second to no writer in *raffinement* of imagination. Yet we doubt that the gullibility of the one or the imagination of the other would have been equal to swallowing or inventing anything equal to this seriocomic defeat of a eugenic marriage law in twentieth century Wisconsin.
>
> Were not the subject so desperately ticklish, one might long for the pen of an Aristophanes, a Plautus or a Jonson to turn this sex adventure into a blazing satire on the folly of half-baked and half-enforced legislation.

The whole medical profession suffers when one or more of its members persist in slipshod and unethical methods. I will say this to the credit of the Wisconsin medical societies, both county and state, that not one of the five physicians now awaiting trial for abortion, here in Milwaukee, belongs to the medical societies. And I am glad to say that this speaks well for the morality of the greater number of the medical men in Wisconsin.

A. J. Caffrey, M.D., Milwaukee, Wis.

The Tuberculosis Problem

To the Editor.—I am extremely interested in the articles on "The Tuberculosis Problem" which have been appearing in The Journal (Department of Therapeutics, March 14 to April 25). They contain a great deal of information of importance to the general medical profession and are very timely. I disagree, however, with a statement which is of far-reaching significance and which should not be left unchallenged.

In considering a case of tuberculosis in a home as a source of infection to those who live in it, great emphasis is laid on the communicability of the disease to children. Close contact of children with tuberculous persons is regarded, in this article, as a factor in the incidence of active tuberculosis among children, which infection either results fatally or, in a majority of cases, becomes latent, these latent foci constituting the determining factor in the production of active tuberculosis in adults.

In emphasizing this theory of von Behring's, the article falls into the error of minimizing the danger of tuberculous infection in adult life to the point of suggesting that even the term "communicable" ought to be modified or more carefully explained. It is our experience, however, that close contact with uncontrolled "open" cases of tuberculosis in homes does lead to infection of adults, as shown by the everyday experiences of tuberculosis workers, dispensaries, sanatoriums, etc., all over the land.

The tentative theory (not fully proved) is that infection in childhood is *one* of the important factors determining the incidence of tuberculosis among adults. The repeated infections of the adult by an uncontrolled tuberculous case in a home is, however, also a factor of importance in causing the existing prevalence of tuberculosis. The implantation of the germ in the child should be prevented; it should also be prevented in the adult (be he a carrier of latent foci or not). Should the statement made in your Department of Therapeutics be correct, patients with advanced cases of tuberculosis ought to be hospitalized only in instances in which children are in contact with the source of infection. Our present arrangement is designed, however, to give protection not only to the child but to the adult as well.

I greatly appreciate the educational value of these important articles on the tuberculosis problem, and yet I consider it my duty to raise the question in reference to the abovementioned important point.

Theodore B. Sachs, M.D., Chicago.

[Comment.—It was not intended to convey the idea that open tuberculosis cases could not convey infection to adults, and it was hoped that the entire discussion emphasized the proper care that such patients should receive, not only for their own sake, but also to prevent the infection of others. It was intended to declare the belief that by far the greatest danger in infection of others is to children, and that an intelligent adult, under medical supervision and having received, and acting under careful instructions, is a menace to no one, unless he is helpless and in bed, in which case it is the nurse who should act under instructions.

Dr. Sachs' letter is welcomed, as evidently these points were not made plain.—Ed.]

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

MEDIUMS FOR OIL-IMMERSION LENSES

To the Editor:—Is there any reason why one should not use glycerin with an oil-immersion lens in microscopy? It is much easier to clean from the lens and slide after using than the usual cedar oil. Unless it can be harmful to the lens in some manner, I do not see why it is not more in use. I have used it for some time.

M. A. LEE, M.D., Superior, Wis.

ANSWER.—Objectives intended for immersion are specially corrected for the specific medium to be employed. Four mediums have been used: water, cedar oil, monobromid of naphthalin and glycerin. Water has a refractive index of 1.33, and when used with ordinary glass, must have a correction applied. The objective will not receive so many rays from the object when used with cedar oil, whose refractive index is 1.52, nearly the same as that of the glass employed for the cover-glass. Monobromid of naphthalin has a higher refractive index, 1.567, and special flint cover-glasses must be employed with it. Glycerin has a refractive index of 1.478, which is not far from the refractive index of the ordinary cover-glass, so that it probably could be used without much inconvenience.

THE MOSZKOWICZ TEST

To the Editor:—Please describe the methods of Moszkowicz and Sandrock for examination to determine where to operate in gangrene, etc.

HORACE FOX, M.D., Bath, Me.

ANSWER.—The test of Moszkowicz is applied as follows: The affected limb is elevated until a marked pallor of the skin occurs. A circular, broad, elastic bandage is applied around the thigh as high up as possible, and the constrictor is allowed to remain in place five minutes. When the constrictor is removed, the hyperemic blush spreads over the limb but is much less intense as the ischemic areas of the foot or leg are approached. The contrast between the red and pale areas is marked in proportion with the extent of the arterial obstruction. An operation within the pale zone is likely to end in a sloughing of the flaps, but amputation may be made with safety anywhere within the line of the pink or hyperemic skin. This method is not accepted as reliable by all authorities.

We are unable to give the Sandrock method.

STATES WHICH RECIPROCATE WITH MAINE

To the Editor:—What states have reciprocal relations with Maine?

F. J. M.

ANSWER.—Maine has reciprocal relations with Arkansas,* Colorado,* Delaware,* District of Columbia,* Georgia, Illinois,* Indiana, Iowa, Kansas, Kentucky, Louisiana,* Maryland,* Michigan, Minnesota,* Missouri, Nebraska, New Jersey,* Ohio, South Carolina, Tennessee, Texas,* Utah, Vermont,* Virginia,* Wisconsin and Wyoming.* Those marked with an asterisk (*) reciprocate on the basis of an examination only; the others reciprocate on the basis either of an examination or of a diploma from a reputable medical college without examination if the diploma and license were granted prior to July 1, 1901.

An Estimate of the Scientist.—When the intellectual history of this time comes to be written, nothing I think will stand out more strikingly than the empty gulf in quality between the superb and richly fruitful scientific investigations that are going on and the general thought of other educated sections of the community. I do not mean that the scientific men are as a whole a class of supermen, dealing with and thinking about everything in a way altogether better than the common run of humanity, but that in their own field they think and work with an intensity, an integrity, a breadth, boldness, patience, thoroughness and faithfulness that (excepting only a few artists) puts their work out of all comparison with any other human activity.—H. G. Wells, "Marriage."

Book Notices

Chronic Colitis: Its Causation, Diagnosis and Treatment. By George Herschell, M.D., and Adolphe Abrahams, M.D., Medical Registrar to the London Temperance Hospital. Cloth. Price, $2. Pp. 273. New York: Longmans, Green & Co., 1914.

A careful study of a single disease by the refined diagnostic means of modern research is presented in this book. The physician of a past generation could shrewdly guess that his patient who complained of chronic diarrhea with pain and occasionally bloody stools was suffering from colitis, but he did not dream of such a condition when constipation was the principal symptom. In such cases he had no reliable means of examination which would determine whether or not his surmise was correct. The symptoms were often referred to nervousness and, indeed, a large number of cases passed under the name of colica mucosa as due to a purely nervous secretion of mucus. The authors base their description of the disease on the results of examinations by the sigmoidoscope and the laboratory methods of examination of the feces. The methods of diagnosis are systematic, but sometimes lacking in detail. Although the statement is made that "one can not only palpate the colon, but can determine its exact position, its condition of emptiness or fulness, etc.," no directions for making such an examination are given except a reference to the work of Vincent. The directions for the examination of the feces are reasonably full. About half the work is given to the subject of treatment. The removal of a probable cause is insisted on, and due credit is given to diseases of the teeth, the nasopharynx and the stomach as causes of the intestinal affection. The consideration of the diet is especially thorough and detailed. Minute directions are given for the use of enemas, irrigations, etc. The question of the possibility of entering the colon by a soft tube is presented and the opposing opinions of Combe and of Kemp are quoted, but no decision is given. A long list of medicinal agents is mentioned which are supposed to act as intestinal antiseptics, and their actions and classification according to Combe are described. Here again the opinion of Combe is quoted, but the authors give no final decision, although they seem inclined to favor the opinion that these agents act as efficient intestinal antiseptics. The untenability of the opinion that charcoal cures flatulence by absorbing gases is recognized, but the authors think that it is efficient against flatulence by some unexplained action on the intestinal wall. Practically no proprietaries are mentioned except such as have received general approval like ichthyol, aspirin, etc. The authors state that so far as they know theirs is the first English manual that has appeared on this subject, and they are to be congratulated on having produced a book of so high a grade which at the same time is so adequately adapted to the needs of the general practitioner. It is gratifying to note the care with which they acknowledge the sources of their information and the considerable extent to which they have made use of the work of American investigators.

A Text-Book of Histology Arranged on an Embryological Basis. By Dr. Frederic T. Lewis, Assistant Professor of Embryology at the Harvard Medical School and Dr. Philipp Stöhr. Second Edition. Cloth. Price, $3 net. Pp. 539, with 495 illustrations. Philadelphia: P. Blakiston's Son & Co., 1914.

This book, which is largely the work of Lewis and retains but little of Stöhr's original text, is arranged on an embryologic basis, the development of each organ being described as an introduction to the study of its microscopic structure in the adult. This method of presentation, which is a new departure in text-books on histology, is logical and pedagogically practicable. It proceeds from simple arrangements to those which are complex, and it emphasizes fundamental features in distinction from those which are secondary. Anatomy is likewise accorded an important place. References to a selection of recent papers are given. The general arrangement is similar to that of other works on this subject. There is a chapter on microscopic technic. The illustrations are numerous and good.

Medicolegal

Construction of Pure-Food Law with Reference to Adulteration

(United States vs. Lexington Mill & Elevator Co. (U. S.), 34 Sup. Ct. R. 337)

The Supreme Court of the United States says that the statute on its face shows that the primary purpose of Congress was to prevent injury to the public health by the sale and transportation in interstate commerce of misbranded and adulterated foods. The legislation, as against misbranding, intended to make it possible that the consumer should know that an article purchased was what it purported to be; that it might be bought for what it really was, and not on misrepresentations as to character and quality. As against adulteration, the statute was intended to protect the public health from possible injury by adding to articles of food consumption poisonous and deleterious substances which might render such articles injurious to the health of consumers.

The fifth subdivision of Section 7 provides that food shall be deemed to be adulterated "if it contain any added poisonous or other added deleterious ingredient which may render such article injurious to health." Congress has here definitely outlined its inhibition against a particular class of adulteration. It is not required that the article of food containing added poisonous or other added deleterious ingredients must affect the public health, and it is not incumbent on the government in order to make out a case to establish that fact. The act has placed on the government the burden of establishing, in order to secure a verdict of condemnation under the statute, that the added poisonous or deleterious substances must be such as may render such article injurious to health. The word "may" is here used in its ordinary and usual signification.

In thus describing the offense, Congress doubtless took into consideration that flour may be used in many ways, in bread, cake, gravy, broth, etc. It may be consumed, when prepared as a food, by the strong and the weak, the old and the young, the well and the sick; and it is intended that if any flour, because of any added poisonous or other deleterious ingredient, may possibly injure the health of any of these, it shall come within the ban of the statute. If it cannot by any possibility, when the facts are reasonably considered, injure the health of any consumer, such flour, though having a small addition of poisonous or deleterious ingredients, may not be condemned under the act.

This court affirms the judgment of the circuit court of appeals reversing a decree condemning certain flour as adulterated by bleaching because the trial court permitted the statute to be read without the final and qualifying words concerning the effect of the article on health, rendering a new trial necessary.

Time for Commencement of Action for Being Made a Morphin User

(Gillmore vs. Gillmore (Kan.), 137 Pac. R. 958)

The Supreme Court of Kansas holds that an action for damages because of the defendant having induced the plaintiff to become a user of morphin, in ignorance of its nature, is not for relief on the ground of "fraud," within the meaning of that term as used in the statute of limitations. The running of the statute of limitations, on an action for damages because of the defendant having induced the plaintiff to become a user of morphin, is not wholly suspended by the fact that the plaintiff, knowing the manner in which the habit was induced, and having acquired knowledge of the effects of the drug, has been so affected mentally as not to be capable of protecting his own interests. Such an action can be brought only within one year from the time that mental capacity is restored, under the Kansas statute of limitations.

AMERICAN ASSOCIATION OF PHYSICIANS

Twenty-Ninth Annual Meeting, held at Atlantic City, N. J., May 12 and 13, 1914

The President, DR. SIMON FLEXNER, New York, in the Chair

Officers

The following officers were elected for the ensuing year: president, Dr. S. J. Meltzer, New York; vice-president, Dr. Henry Sewall, Denver; secretary, Dr. George M. Kober, Washington, D. C., reelected; recorder, Dr. Thomas McCrae, Philadelphia, reelected; treasurer, Dr. J. P. Crozer Griffith, Philadelphia, reelected.

Advance in Medical Knowledge

DR. SIMON FLEXNER: The extension of the boundaries of knowledge has compelled medical colleges to become departments of universities. This rapid extension of knowledge coincided with the active pursuit of physiology, pathology, bacteriology and pharmacology, either alone or in association with clinical studies for which special laboratories and institutes came to be established. Independent institutions for medical research have exercised a distinct influence on medical practice, but the foundation of these institutions was impossible until medical schools furnished an adequate supply of students whose training approximated that of the older European countries. All these conditions have acted more powerfully on clinical teaching. The professor of medicine in the university medical school ceased long ago to be a general practitioner. The function of the clinical teacher has been newly defined within one or two decades. The American Association of Physicians has sympathized with every movement affecting the progress of medical education, and it favors this latter step with the single hope that if it be in the real interest of medical progress, it may be given a chance to succeed.

Chronic Interstitial Gastritis

DR. JOSEPH SAILER, Philadelphia: A man, aged 45, had been subjected to various forms of medical treatment, without avail. An exploratory operation showed the condition of the stomach entirely in accord with the clinical picture. The stomach walls were very thick. The stomach was adherent posteriorly and around the pylorus. Gastro-enterostomy would have been difficult, in addition to giving no definite relief. There were no enlarged glands along the lesser curvature, but the adhesions were dense along the greater curvature, and a definite gland mass could not be felt. There was no evidence of metastasis. The abdomen was closed and the patient made a satisfactory recovery from the exploratory operation.

DISCUSSION

DR. DAVID RIESMAN, Philadelphia: Recently I saw a typical case of leather-bottle stomach which was very malignant, because the patient had cachexia and ascites. Both of these conditions in this case were sufficient to determine that the condition was cancerous. The man died in a few weeks. There were no evidences of metastases in the liver, and the liver was not enlarged at any time. Another case that came to necropsy showed no metastases from any of the viscera, but marked enlargement of the glands along the greater curvature of the stomach.

The Nature of Peristalsis and the Action of Magnesium Sulphate

DR. S. J. MELTZER, New York: Peristalsis is a complicated condition in which the phenomenon of inhibition plays an important part, and magnesium sulphate acts by affecting this inhibitory force.

Clinical Study of One Thousand Cases of Gastric-Cancer

DR. JULIUS FRIEDENWALD, Baltimore: The cases occurred in 10,416 patients, affected with various gastro-intestinal disturbances. The maximum liability to the disease occurred between the fortieth and sixtieth years. The greatest proportion of cases occurred in males, 588 to 412 females. A hereditary history of cancer appeared in 9.4 per cent. of cases, a history of trauma in 1.9 per cent., and anemia was present in 82 per cent. Chronic endocarditis was present in 11.4 per cent., arteriosclerosis in 69.6 per cent. A history of former indiscretions in diet was obtained in 32.1 per cent.; of alcoholism in 15.2 per cent.; of syphilis in 7.9 per cent.; hyperchlorhydria in 4.9 per cent.; hypochlorhydria in 2.8 per cent., and anacidity in 89.2 per cent. Lactic acid was present in 81.9 per cent. Oppler-Boas bacilli were obtained in 79.3 per cent. Dysphagia existed in 6.9 per cent. of all cases. Loss of weight existed in 88.5 per cent. Anorexia was present in 89.3 per cent., and vomiting in the same percentage. Occult blood was present in the stools in 92.5 per cent. Masses in the form of tumors were detected in 71.9 per cent. Dilatation of the stomach existed in 46.7 per cent. Perforation occurred in 2.3 per cent. Metastasis existed in 67.2 per cent.

When and How to Use Tuberculin Preparations in Private Practice

DR. S. SOLIS-COHEN, Philadelphia: My modification of Latham's method: tuberculin residue (T. R.) triturated with milk-sugar is given with skim-milk, whey or beef-juice. The initial dose is 0.000001 mg. Both subjective and objective symptoms of reaction are watched for. The dose is repeated once or twice weekly, according to result. It is gradually increased by increments of 0.000001 mg. to the reaction-point, and then dropped one point lower, and so continued for some weeks. Later, a further increase is attempted, and if reaction is not shown, is proceeded with in a similar gradual way. The arbitrary increment of 0.000001 mg. is maintained during this remittent progression, until 0.0001 mg. has been reached. After that, the increment may be raised to 0.00001. Thus by successive stages, a maximum dose is attained at a point determined for each individual by all the factors in the case, including the rapidity of increase, character and intensity of reaction and maintenance of tolerance, as well as the focal and general signs of improvement. The treatment is continued with intermissions, for many months, and may be resumed, if necessary, from time to time over a period of years.

In the majority of advanced cases tuberculin is likely to be harmful. Experienced observers may employ it cautiously under conditions that seem to call for its use, but others should avoid it, especially in cases which show a tendency to continuous fever, or in which there is, or has been recently, active softening. In the great bulk of early cases it is needless. Under proper treatment, medicinal as well as hygienic recovery will take place without it. Its field of action is in the treatment of cases which have not passed beyond the stage of infiltration and which have shown a certain degree of improvement under proper food, fresh air, judicious rest and exercise, and other approved measures, including the right drugs, but in which improvement becomes sluggish or ceases, or retrogression takes place. The slight additional stimulus afforded by an appropriate tuberculin preparation administered at well-chosen times, and in correct dosage, will often reawaken the defensive and restorative processes of the organism, and be followed by complete recovery.

Construction of Pure-Food Law with Reference to Adulteration

(United States vs. Lexington Mill & Elevator Co. (U. S.), 34 Sup. Ct. R. 337)

The Supreme Court of the United States says that the statute on its face shows that the primary purpose of Congress was to prevent injury to the public health by the sale and transportation in interstate commerce of misbranded and adulterated foods. The legislation, as against misbranding, intended to make it possible that the consumer should know that an article purchased was what it purported to be; that it might be bought for what it really was, and not on misrepresentations as to character and quality. As against adulteration, the statute was intended to protect the public health from possible injury by adding to articles of food consumption poisonous and deleterious substances which might render such articles injurious to the health of consumers.

The fifth subdivision of Section 7 provides that food shall be deemed to be adulterated "if it contain any added poisonous or other added deleterious ingredient which may render such article injurious to health." Congress has here definitely outlined its inhibition against a particular class of adulteration. It is not required that the article of food containing added poisonous or other added deleterious ingredients must affect the public health, and it is not incumbent on the government in order to make out a case to establish that fact. The act has placed on the government the burden of establishing, in order to secure a verdict of condemnation under the statute, that the added poisonous or deleterious substances must be such as may render such article injurious to health. The word "may" is here used in its ordinary and usual signification.

In thus describing the offense, Congress doubtless took into consideration that flour may be used in many ways, in bread, cake, gravy, broth, etc. It may be consumed, when prepared as a food, by the strong and the weak, the old and the young, the well and the sick; and it is intended that if any flour, because of any added poisonous or other deleterious ingredient, may possibly injure the health of any of these, it shall come within the ban of the statute. If it cannot by any possibility, when the facts are reasonably considered, injure the health of any consumer, such flour, though having a small addition of poisonous or deleterious ingredients, may not be condemned under the act.

This court affirms the judgment of the circuit court of appeals reversing a decree condemning certain flour as adulterated by bleaching because the trial court permitted the statute to be read without the final and qualifying words concerning the effect of the article on health, rendering a new trial necessary.

Time for Commencement of Action for Being Made a Morphin User

(Gillmore vs. Gillmore (Kan.), 137 Pac. R. 958)

The Supreme Court of Kansas holds that an action for damages because of the defendant having induced the plaintiff to become a user of morphin, in ignorance of its nature, is not for relief on the ground of "fraud," within the meaning of that term as used in the statute of limitations. The running of the statute of limitations, on an action for damages because of the defendant having induced the plaintiff to become a user of morphin, is not wholly suspended by the fact that the plaintiff, knowing the manner in which the habit was induced, and having acquired knowledge of the effects of the drug, has been so affected mentally as not to be capable of protecting his own interests. Such an action can be brought only within one year from the time that mental capacity is restored, under the Kansas statute of limitations.

AMERICAN ASSOCIATION OF PHYSICIANS

Twenty-Ninth Annual Meeting, held at Atlantic City, N. J., May 12 and 13, 1914

The President, Dr. Simon Flexner, New York, in the Chair

Officers

The following officers were elected for the ensuing year: president, Dr. S. J. Meltzer, New York; vice-president, Dr. Henry Sewall, Denver; secretary, Dr. George M. Kober, Washington, D. C., reelected; recorder, Dr. Thomas McCrae, Philadelphia, reelected; treasurer, Dr. J. P. Crozer Griffith, Philadelphia, reelected.

Advance in Medical Knowledge

Dr. Simon Flexner: The extension of the boundaries of knowledge has compelled medical colleges to become departments of universities. This rapid extension of knowledge coincided with the active pursuit of physiology, pathology, bacteriology and pharmacology, either alone or in association with clinical studies for which special laboratories and institutes came to be established. Independent institutions for medical research have exercised a distinct influence on medical practice, but the foundation of these institutions was impossible until medical schools furnished an adequate supply of students whose training approximated that of the older European countries. All these conditions have acted more powerfully on clinical teaching. The professor of medicine in the university medical school ceased long ago to be a general practitioner. The function of the clinical teacher has been newly defined within one or two decades. The American Association of Physicians has sympathized with every movement affecting the progress of medical education, and it favors this latter step with the single hope that if it be in the real interest of medical progress, it may be given a chance to succeed.

Chronic Interstitial Gastritis

Dr. Joseph Sailer, Philadelphia: A man, aged 45, had been subjected to various forms of medical treatment, without avail. An exploratory operation showed the condition of the stomach entirely in accord with the clinical picture. The stomach walls were very thick. The stomach was adherent posteriorly and around the pylorus. Gastro-enterostomy would have been difficult, in addition to giving no definite relief. There were no enlarged glands along the lesser curvature, but the adhesions were dense along the greater curvature, and a definite gland mass could not be felt. There was no evidence of metastasis. The abdomen was closed and the patient made a satisfactory recovery from the exploratory operation.

DISCUSSION

Dr. David Riesman, Philadelphia: Recently I saw a typical case of leather-bottle stomach which was very malignant, because the patient had cachexia and ascites. Both of these conditions in this case were sufficient to determine that the condition was cancerous. The man died in a few weeks. There were no evidences of metastases in the liver, and the liver was not enlarged at any time. Another case that came to necropsy showed no metastases from any of the viscera, but marked enlargement of the glands along the greater curvature of the stomach.

The Nature of Peristalsis and the Action of Magnesium Sulphate

Dr. S. J. Meltzer, New York: Peristalsis is a complicated condition in which the phenomenon of inhibition plays an important part, and magnesium sulphate acts by affecting this inhibitory force.

Clinical Study of One Thousand Cases of Gastric-Cancer

Dr. Julius Friedenwald, Baltimore: The cases occurred in 10,416 patients, affected with various gastro-intestinal disturbances. The maximum liability to the disease occurred between the fortieth and sixtieth years. The greatest proportion of cases occurred in males, 588 to 412 females. A hereditary history of cancer appeared in 9.4 per cent. of cases, a history of trauma in 1.9 per cent., and anemia was present in 82 per cent. Chronic endocarditis was present in 11.4 per cent., arteriosclerosis in 69.6 per cent. A history of former indiscretions in diet was obtained in 32.1 per cent.; of alcoholism in 15.2 per cent.; of syphilis in 7.9 per cent.; hyperchlorhydria in 4.9 per cent.; hypochlorhydria in 2.8 per cent., and anacidity in 89.2 per cent. Lactic acid was present in 81.9 per cent. Oppler-Boas bacilli were obtained in 79.3 per cent. Dysphagia existed in 6.9 per cent. of all cases. Loss of weight existed in 88.5 per cent. Anorexia was present in 89.3 per cent., and vomiting in the same percentage. Occult blood was present in the stools in 92.5 per cent. Masses in the form of tumors were detected in 71.9 per cent. Dilatation of the stomach existed in 46.7 per cent. Perforation occurred in 2.3 per cent. Metastasis existed in 67.2 per cent.

When and How to Use Tuberculin Preparations in Private Practice

Dr. S. Solis-Cohen, Philadelphia: My modification of Latham's method: tuberculin residue (T. R.) triturated with milk-sugar is given with skim-milk, whey or beef-juice. The initial dose is 0.000001 mg. Both subjective and objective symptoms of reaction are watched for. The dose is repeated once or twice weekly, according to result. It is gradually increased by increments of 0.000001 mg. to the reaction-point, and then dropped one point lower, and so continued for some weeks. Later, a further increase is attempted, and if reaction is not shown, is proceeded with in a similar gradual way. The arbitrary increment of 0.000001 mg. is maintained during this remittent progression, until 0.0001 mg. has been reached. After that, the increment may be raised to 0.00001. Thus by successive stages, a maximum dose is attained at a point determined for each individual by all the factors in the case, including the rapidity of increase, character and intensity of reaction and maintenance of tolerance, as well as the focal and general signs of improvement. The treatment is continued with intermissions, for many months, and may be resumed, if necessary, from time to time over a period of years.

In the majority of advanced cases tuberculin is likely to be harmful. Experienced observers may employ it cautiously under conditions that seem to call for its use, but others should avoid it, especially in cases which show a tendency to continuous fever, or in which there is, or has been recently, active softening. In the great bulk of early cases it is needless. Under proper treatment, medicinal as well as hygienic recovery will take place without it. Its field of action is in the treatment of cases which have not passed beyond the stage of infiltration and which have shown a certain degree of improvement under proper food, fresh air, judicious rest and exercise, and other approved measures, including the right drugs, but in which improvement becomes sluggish or ceases, or retrogression takes place. The slight additional stimulus afforded by an appropriate tuberculin preparation administered at well-chosen times, and in correct dosage, will often reawaken the defensive and restorative processes of the organism, and be followed by complete recovery.

DISCUSSION

Dr. Abraham Jacobi, New York: I have used tuberculin in doses of from 0.00001 up to 0.0002, and I have never seen any unpleasant symptoms. I have given it in combination with other treatments or remedies. My routine treatment in chronic cases of pulmonary tuberculosis consists in the internal administration of guaiacol and arsenic with tuberculin, and I have observed no disagreeable symptoms which I could attribute to the tuberculin.

LOUISIANA STATE MEDICAL SOCIETY

Thirty-Fifth Annual Meeting, held at New Orleans, April 20-23, 1914

(Concluded from page 1587)

Autoplastic Bone-Grafting

Dr. John F. Oechsner, New Orleans: Autogenous transplantation of bone is an established surgical procedure. Whether dependent for growth on periosteum, or on the graft as a scaffolding for the development of blood-vessels, transplants for the present should be provided with both, particularly plenty of periosteum. Non-absorbable suture material had better be avoided, whenever possible, dovetailing and absorbable material being used in their stead. It is highly probable that organized bone-tissue will take the place of foreign material now used in fractures. Bone-grafting should never be done in the presence of an active infection. The most rigid asepsis should be exercised. Bone-grafts owe their virility and ultimate success probably to the rapidity of blood-vessel development plus the presence of osteoblasts wherever they may be.

Modern Diagnostic Methods in Genito-Urinary Surgery

Dr. H. W. E. Walther, New Orleans: The foundation of diagnostic methods in genito-urinary surgery is urinalysis. We have in the Buerger cysto-urethroscope an instrument by means of which it is possible to obtain absolutely true pictures of the bladder-neck and the posterior urethra. The relatively modern progress attained in perfecting the technic of kidney, ureteral and vesical surgery has made the use of the cystoscope and the ureteral catheter a necessity in the diagnosis of all bladder, ureteral and kidney lesions as well as in the differential diagnosis of many abdominal conditions. The newer methods for determining the functional capacity or activity of the kidneys include cryoscopy, the estimation of the electrical conductivity of the urine, the production of temporary glycosuria by the subcutaneous injection of phlorizin, the production of experimental polyuria and chromocystoscopy, that is, the elimination by the kidneys of certain color substances, as methylene blue, indigocarmin and phenolsulphonephthalein. Pyelography is helpful in demonstrating the normal kidney pelvis; the amount of dilatation of the pathologic pelvis; the position of the outlet of the pelvis of the kidney; the condition of the calices and pyramids; localization of shadows within the kidney; the differentiation of abdominal tumors and extrarenal shadows; congenital deformities of the kidney, and the condition of the ureters.

Treatment of Bladder Tumors by the High-Frequency Current

Dr. Joseph Hume and **Dr. Samuel Logan**, New Orleans: We have treated ten cases embracing almost every form of tumor encountered in bladder growths. In 4 cases of papilloma, 3 patients are apparently well, and 1 has just begun treatment; in 4 cases of malignant papilloma, 1 patient has gone home apparently cured, 2 are still under treatment, and 1 died during treatment from nephritis; in 2 cases of cancer, one patient dying from nephritis, the tumor when last seen was controlled; and one patient is still under treatment, seemingly better.

Pituitary Extract in Obstetric Practice

Dr. M. Thomas Lanaux, New Orleans: Pituitary extract should not be given in normal labor. Its use should be limited to cases of primary or secondary inertia, to postpartum hemorrhages and in cesarean sections as a substitute for ergot. In cases of inertia in any stage of labor it should not be employed unless anesthesia is at hand for immediate use and preparation has been made for immediate delivery. When obstructions exist in the second stage of labor, small tentative doses of pituitary extract can be given, not with complete delivery by means of the drug in view, but to bring the head within easy reach of a single simple forceps delivery. In the second stage of labor it is a most valuable addition to our resources for the treatment of inertia.

Cancer

Dr. C. Jeff Miller, New Orleans, introduced the following resolution, which was adopted:

> *Resolved*, That the society approves of a public educational campaign for the control of cancer and endorses the purposes of the American Society for the Control of Cancer.
>
> It urges the State Board of Health to open its laboratories for the examination of tissue and to supply through its bulletin the necessary details for collecting and mailing specimens, and that the society appoint a permanent committee on cancer that shall collect data, furnish as a committee articles for the lay press, and encourage the study of cancer throughout the state.

Dr. F. W. Parham, New Orleans: Primary cancer of the small intestine in at least 40 per cent. of cases gives rise to obstruction much earlier than in the case of the large intestine. Sixteen cases of operation before complete occlusion gave a mortality of 18.7 with 13 cures; 10 cases after occlusion gave 70 per cent. mortality with only 3 cures.

Dr. Isadore Dyer, New Orleans: It is difficult to catalogue all the lesions of the skin which might be listed under the title of precancerous lesions of the skin, for the reason that experience shows that almost any inflammatory process with destruction of tissue may end in carcinoma.

Dr. William H. Harris, New Orleans: A specific histopathologic picture for the so-called precancerous stage has not been recognized by pathologists, but a careful cooperation between the surgeon and the pathologist in such considerations is capable of bringing forward information of equal value to the patient as if the precancerous stage were a definite entity.

Dr. William Kohlmann, New Orleans: Since 1908 I have performed the radical (Wertheim) operation for carcinoma of the uterus in thirty-two cases, and a good number of these patients have been far beyond the stage at which a cure could be expected. Only a very few of them have been clearly within the limit that may be called operable, and these have been operated on only in the last three years. In the years 1908 and 1909 I operated on thirteen patients; three died, three were temporarily improved, and seven were free from symptoms for one or two years. They were all advanced cases.

Gunshot Wounds of the Abdomen

Dr. J. G. Martin, Lake Charles: I have operated in two cases successfully. One had a perforation of the small intestine and of the bladder. The other had three perforations of the ileum and one of the transverse colon. In the latter case, in which I operated about one hour after the receipt of the injury, the patient would have died from hemorrhage, if not from peritonitis, as active bleeding was going on from one of the mesenteric vessels.

Treatment of Compound Fractures

Dr. L. B. Crawford, New Orleans: I favor the use of Lane plates in the treatment of these fractures. My results in four cases strengthen my conviction that this method of treating compound fractures is worthy of some note.

Postoperative Management of Surgical Cases

Dr. E. Denegre Martin, New Orleans: Results depend on a more intimate knowledge of patients, the better management of operations, and on the exercise of judgment, which can be gained only by experience—not the mistaken experience of the useless administration of unnecessary drugs, but the experience of non-interference.

THE AMERICAN DERMATOLOGICAL ASSOCIATION

Thirty-Eighth Annual Meeting, held in Chicago, May 14-16, 1914

The President, Dr. James MacFarlane Winfield, Brooklyn, in the Chair

Officers Elected

The following officers were elected for the coming year: president, Dr. S. Pollitzer, New York; vice-president, Dr. Martin F. Engman, St. Louis; secretary and treasurer, Dr. Oliver S. Ormsby, Chicago. Place of next meeting, New York.

Teaching of Dermatology—The Care of Lepers

Dr. James MacFarlane Winfield, New York: Dermatology is coming into its own, and is being recognized among medical men as one of the most scientific, difficult and important of the medical specialties; but in spite of that even now there are comparatively few schools that teach the subject properly. The time has come when we of dermatologic thought and teaching should make a united effort to improve and unify the teaching of skin diseases. It should be our endeavor to do everything possible to correct the custom that still prevails in many of our medical schools of having syphilis taught by the chair of genito-urinary diseases. Granting that syphilis is a constitutional systemic disease, the cutaneous specialist is the one who is trained to recognize its varied manifestations. Is it not logical that he would also be better able to teach it than any one else? We may look still farther beyond, and begin to advocate now the establishment of a special department and chair of syphilology in all of our medical schools and hospitals, in order that the whole subject may be taught systematically by men especially trained for this work. Owing to the influx of people from those countries where leprosy is endemic, and the increased number of these cases in the United States it would seem to me that this association should join hands with other medical bodies in urging on the United States government the necessity for a national law and the establishment of a national home or homes for lepers. I would therefore suggest that a committee of this association be created to draft a memorial to be presented to the President of the United States, and the Senate and House of Representatives, setting forth the dangers of the leper at large, and urging the need of his detention in a place under national control, where he could receive the proper care, and where scientific investigations could be carried on with a view to the relief of the unfortunate himself, the prevention of the further spread of the disease, and the eventual eradication of it from the world.

[In accordance with this recommendation a permanent committee on leprosy was appointed and the association adopted resolutions as recommended by the president.]

PARONYCHIA: ETIOLOGY AND TREATMENT

Dr. Howard Morrow and Dr. A. W. Lee, San Francisco: In considering the subject of paronychia, we shall limit it to an inflammation of the nail-bed and nail-fold due to organisms apart from those considered to be the etiologic factors in lues, tuberculosis, tinea, blastomycosis, etc. Of sixteen cases studied by us, two were acute and fourteen of long standing, and all have been caused, as shown culturally, by the *Staphylococcus pyogenes albus.* No definite conclusions could be drawn from this limited number of cases as to whether age, sex or occupation bears any distinct relation to the pathologic condition. Thirteen of these cases remained as uncomplicated paronychia, while three progressed to onychia, with exfoliation of the nail. In only one case did the pathologic condition involve the feet, and in this case all of the toes were affected. Of the hand cases, all the nails were involved in only two instances, and the remainder varied from one to six diseased nails. In fourteen of the cases the condition started about the nails and remained confined to that location until cured. In two cases the disease was secondary to pyogenic dermatitis on other portions of the body. In each case it was possible to obtain from the lesions a pure culture of the *Staphylococcus pyogenes albus,* and, singularly enough, no other organisms grew on the culture mediums employed, namely, blood-serum and agar. Notwithstanding this experience, it is probable that the *Staphylococcus pyogenes aureus* is responsible for a certain percentage of cases.

For some years we have followed the treatment by ointments, compresses, powders and, in recent years, by vaccines. A large percentage of the cases treated by these measures have given unsatisfactory results, probably because of the fact that aside from vaccines these applications do not penetrate into the affected areas. In our hands vaccine therapy did not give the same satisfactory results as the method to be described. The preparation used with the greatest amount of success was a saturated solution of chrysarobin in chloroform. This combination was found more satisfactory than the usual preparation of chrysarobin with a fatty base. The reason for using chloroform as a menstruum is that it has a high tissue-penetrating index. The reason for using chrysarobin is that it has a high staphylococcic bactericidal influence. The following method of using this preparation was employed: The plica unguis should be raised from the nail and the affected area swabbed with the chrysarobin preparation. This should be done once daily until there is no longer any pus formation. The latter condition usually subsides after a few applications. It must be remembered, however, that chrysarobin occasionally causes an intense dermatitis, even after one application, and in such cases this treatment should be pursued with caution. By this method all of our patients were cured in from one to three weeks.

DISCUSSION

Dr. Charles J. White, Boston: Paronychia is not a particularly common infection in the Massachusetts General Hospital, but when we do see it, it is very apt to be in Jewish housewives. The explanation for this apparently is that they are not allowed to use soap in the washing of their dishes for fear that there may be some pig fat in the composition of the soap.

Dr. A. Ravogli, Cincinnati: I have seen a great many cases of eczema of the nail-bed, which I would not exactly call paronychia, because there was not suppuration, but only a little oozing, with swelling and formation of a crust around the nail-bed. These cases I have found to be exceedingly stubborn. I have seen these cases in women employed in factories, and also in those who use the typewriter. The nail has very seldom been affected in these cases. I have also had some cases of true paronychia, with a great deal of suppuration present, and also raising up of the nail, but in these cases incision and removal of the pus have given good results. To correct the eczematous condition referred to, I have found the application of a tincture of iodin, going inside the nail-bed, in the fold of epidermis, a very good measure.

Dr. D. W. Montgomery, San Francisco: A great number of these cases are certainly due to the streptococcus. In order to get a culture of the streptococcic infective agent, though, it is necessary to cultivate it anaerobically. The suggestion made by Jadassohn is of very great importance, namely, to use a platinum needle of exceeding fineness, and drive down into the culture-medium, so that you get an anaerobic cultivation—otherwise it dies out. The suggestion of Sabouraud of cultivating a streptococcus by a blood-medium, excluding the air by a device of an attenuated culture-tube, finely drawn out, in my opinion is not nearly so good as that of Jadassohn. Of course, I recognize also that paronychia is very frequently an accompaniment of eczema.

Dr. George H. Fox, New York: Some one has recently called attention to manicuring the nails and perhaps overrated the evil results from it; but recently the newspapers even in New York have had a number of special articles on the question of forcing the manicurists to obtain licenses, on account of the bad results from their work.

Dr. Howard Morrow, San Francisco: As referred to by Dr. Ravogli, applications of tincture of iodin are very efficacious, as are also those of silver nitrate.

(To be continued)

MEDICAL SOCIETY OF THE STATE OF NEW YORK

One Hundred and Eighth Annual Meeting, held in New York City, April 28-30, 1914

(Continued from page 1686)

Uterine Hemorrhage in Young Girls

Dr. Henry C. Coe, New York: In the absence of any discovered cause for the hemorrhage, local or general, the practitioner is thrown back on experimental medicine and must interrogate rigidly the ductless glands, with more or less doubtful results. Organotherapy must be regarded as the best curative agent along this line. The prognosis must depend on the actual or supposed cause of the condition. Care should be exercised in making caustic applications to the endometrium which are not absolutely controllable and may cause irreparable injury to the delicate organ in subjects of tender years. One of my colleagues has had success in the treatment of obstinate hemorrhage in young women by ligation of the uterine arteries by the vagina which is practically out of the question in young children. I can conceive of cases in which exploratory abdominal section might be elected, even when pelvic examination was negative, but it would be a desperate case indeed in which both ovaries would be removed, not to speak of supravaginal amputation of the uterus.

DISCUSSION

Dr. Harvey P. Jack, Hornell: I have had many cases of hemorrhage in young girls. In several repeated curettements, hygienic measures, parotid gland and thyroids have been administered without relief. These patients seem hardly to recover from the exhausting hemorrhage of one menstruation before another begins. Thyroid extract in small doses, long continued, has proved of great benefit in a few cases, but the agent that has cured every one of these severe cases so far is calcium chlorid. One girl in particular has been brought from a bleached-out nervous wreck to brilliant health by the use of this drug alone.

Sterility in Women

Dr. Willis E. Ford, Utica: Formerly, I was accustomed to use galvanism for a considerable period in these cases to develop the uterus after slitting the posterior neck and divulsion, and I have the history of many cases in which pregnancy followed, even after a lapse of a number of years of sterility. This treatment had to be carried on, however, for several months, and the results were good for a time, but I do not think they compare with the shorter and more simple procedure advocated by Pozzi, especially with respect to the permanency of results. I have been at work long enough to follow the history of many young girls for ten years or more and up to the time of their marriage, and even afterward, and I am convinced that if early and complete drainage is secured through the uterus by this simple procedure in the few cases of cervical deformity, many serious conditions encountered later in life can be prevented and sterility can be avoided in many instances.

Dysmenorrhea

Dr. Rosalie Slaughter Morton, New York: Many gynecologists consider pain at the menstrual period normal. Martin of Germany designates as dysmenorrhea those disturbances which most women experience at the time of menstruation, such as pains in the back, discomfort, continual desire to urinate, etc., and says that these are attendant symptoms which are borne by women prudently. Anteflexion is more commonly associated with pain. I have seen these patients do well with systematic regulation of diet, the drinking of sufficient water, proper hours of sleep and graduated outdoor and indoor exercises, with a strict attention to the minor troubles, bringing these patients from semi-invalidism to efficiency. The working classes are troubled with dysmenorrhea, the percentage depending largely on the development of the individual. Kelly finds 75 per cent. of the college women suffer from dysmenorrhea. I have found poorly nourished, overworked store employees to the extent of 7 per cent. with no pain at the menstrual period. In several young patients with habitual constipation, with no definite pain at the onset of menstruation, with uterus and adnexa normal, but with prolapse of the sigmoid the dysmenorrhea has disappeared after correction of this condition. I recommend postural treatment.

DISCUSSION

Dr. Caroline S. Finley, New York: Most mothers ask me whether or not they should keep their girls in bed the first day during the menstrual period, and I always advise them, if the girls are normal, not to do so. Pain during menstruation may be due to intestinal indigestion. By relieving the constipation you help the mild cases of dysmenorrhea. Again, many patients say that their daughters have leukorrhea. I find on examination that it is simply a serous discharge which comes before the menstrual flow and which is one of its safeguards.

Dr. I. C. Rubin, New York: Theoretically, there is every reason to agree with Dr. Morton on the question of pelvic congestion as causing a lot of pain which is common in dysmenorrhea. If one uses 1/75 grain of atropin, taken in tablets, three times a day, it will bring about the cessation of pain. It must be taken a few hours before the expected period. The atropin is supposed to affect also the uterine muscles. A great many unmarried girls, especially factory girls, suffer more from dysmenorrhea than girls in better social states.

Dr. Mary T. Rose, New York: There is one point which the general practitioner should emphasize, and that is, the congestion in these cases is due to retention in the rectum. We find this especially in our women with dysmenorrheic symptoms. I have found that a good deal of their trouble is primarily retention of fecal matter in the rectum.

Pregnancy in a Tuberculous Woman

Dr. E. Parry, New York: If a woman with tuberculosis is pregnant, she may bear the first pregnancy well, the second pregnancy not so well, and the third one not at all. After parturition, tuberculosis advances rapidly. A woman who has tuberculosis should never become pregnant. Ninety-seven cases of laryngeal tuberculosis are reported in the literature, and of this number ninety patients died. Actively tuberculous patients should be forbidden to marry, or if they do marry they should not become pregnant, or if they become pregnant a therapeutic abortion should be performed.

DISCUSSION

Dr. Ralph W. Lobenstine, New York: Not infrequently pregnancy, especially if too rapidly repeated, will lay the foundation for the development of tuberculosis. That point is generally overlooked. Either pregnancy or the act of parturition aggravates the existing tuberculosis in a large percentage of cases. In von Bardeleben's cases 40 per cent. proved fatal. In my series 50 per cent. of the severe cases terminated fatally within two months after parturition. In the bad cases the patients lose ground rapidly either during labor or within three weeks afterward. During the puerperium the tuberculosis may assume a fulminating character and cause death in a surprisingly short time. The causes of rapid changes post partum are briefly these: prolonged muscular exertion of labor, loss of blood, use of anesthesia, only slightly, and the possibility of renewed toxins or tubercle bacilli being forced into the system from the placental site, all of which are serious and far-reaching in their results. Therapeutic abortion is indicated in the early months in all active cases. Tuberculous persons should, if possible, be forbidden to marry. I feel strongly that if they marry they should be forced to keep from propagating.

Dr. John O. Polak, Brooklyn: I am in full accord with the position taken by Dr. Lobenstine and Dr. Parry regarding tuberculosis and pregnancy as being incompatible in certain stages of the disease, and when we have the indications, as we do in any active process, for interference, I want particularly to speak of the method of emptying the uterus. A considerable experience has shown us that unless the uterus is emptied early in these cases we have a very prolonged abortion, so to speak, by the ordinary expectant plan. Under local anesthesia these patients can be delivered by a vaginal hysterotomy at the third month. Before the eighth week ordinary curettage can be done without the slightest difficulty. After that time, when placental formation has taken place, I would advocate anterior vaginal hysterotomy under local anesthesia or under spinal anesthesia.

Infection with Bacillus Coli Communis Complicating Pregnancy

Dr. Edward P. Davis, Philadelphia: Colon bacillus infection of the large intestine complicating pregnancy is seen in women who have neglected hygienic precaution during pregnancy, who have remained obstinately constipated or who have taken irritant drugs to empty the bowels. The pain is usually localized in the intestine and not in the peritoneum. The colon bacillus may affect the new-born infant, causing icterus and ophthalmia. It may be the cause of septic abortion or of septic infection. In cases of infection of the uterus and appendages by the colon bacillus, as determined by an examination of the contents of the uterus, the treatment does not differ from puerperal infection of other origin, except that a tendency to mixed infection and pus formation must be remembered. In these cases pelvic abscess may be expected and demand drainage.

(To be continued)

MISSISSIPPI STATE MEDICAL ASSOCIATION

Forty-Seventh Annual Meeting held at Columbus, April 14-16, 1914

(Concluded from page 1685)

Some Surgical Conditions Affecting the Biliary Tract

Dr. J. W. Barksdale, Winona: Barring gynecologic and appendix cases, affections of the gall-bladder and bile-ducts are more frequently encountered than any other abdominal ailment. Excepting malignancy and neoplasms, these are all due to bacterial invasion. These cases are exclusively surgical.

DISCUSSION

Dr. John Darrington, Yazoo City: If the gall-bladder is drained, the chances are that the patient will have subsequent trouble again and again until he finally comes to the surgeon for a complete removal. It is extremely important that the surgeon should have a keen appreciation of the condition of the gall-bladder while the abdomen is open.

Dr. W. W. Crawford, Hattiesburg: It is astonishing how many of these cases have gone on year after year without being recognized by us, and how many of them have been treated for indigestion. The symptoms are so like those of ulcer of the stomach that one is pardoned for concluding that the patient has some trouble of that kind, and the great fallacy is that so many of these patients who are dieted improve. The strange thing is that though the bladder may be filled with stones, the patient will improve when placed on a rigid diet, to such a degree that he feels practically well. But he has a series of relapses year in and year out until finally the gall-bladder is either drained or removed.

Prostatectomy

Dr. John Darrington, Yazoo City: The conscientious surgeon approaches these cases with much anxiety, since prostatic enlargement comes with advancing years when degenerative changes have occurred in the vital organs. The choice between the perineal and suprapubic routes should be dependent on the conditions found in the individual case.

DISCUSSION

Dr. J. W. Barksdale, Winona: I have a decided preference for the perineal operation. The patient can get up in from forty-eight to seventy-two hours, and with these old patients that is certainly an advantage. Drainage is another factor, and they can be drained better by the perineal method than by the suprapubic route.

Dr. E. M. Holder, Memphis, Tenn.: The question of the route by which we shall approach the prostate is an important one. The suprapubic route is gaining; men who were favoring the perineal route five or six years ago are now advocating the suprapubic. The operation which appeals to me in most cases is to open the bladder and introduce a catheter through the urethra into the bladder. In very old patients and with cases with the usual bad kidneys and cardiac changes that go along with this trouble, I have found it well to do the operation in the two-step way.

Appendicitis Twenty-Four Hours after the Attack

Dr. L. D. Dickerson, McComb: If fever subsides and pain is relieved, operate after twelve days. If the reverse is the case, operate at once. While waiting, use opiates and ice-bags. The patient should have absolutely nothing by the mouth.

Head Injuries

Dr. G. W. Cale, St. Louis: Fracture of the skull is of serious moment in proportion to the complications that may accompany it. Each individual case of head injury should be studied from the anatomic and physiologic points of view, with the assistance of the Roentgen ray. After a diagnosis is reached, the plan of treatment is usually easily determined.

DISCUSSION

Dr. H. T. Inge, Mobile, Ala.: Treatment of head injuries is not different in many particulars from the treatment of all other forms of injury. The same amount of care in handling a case of head injury will make that injury amenable to treatment just the same as an injury in any other part of the body. In December, in a terrible railway wreck, 169 men were injured. The predominating injuries were head and face injuries. There were several cases in which the brain substance escaped through the wound. There were extensive lacerations of the scalp; and the emergency treatment adopted was not by a surgeon, but by a member of the Hospital Corps, applying the emergency dressing which every United States soldier carries with him. Every soldier hurt in this wreck, as soon as placed in a hospital, was given an immunizing dose of antitetanic serum. His wounds were then dressed by the surgeons and not a single case of infection occurred.

Treatment of Fracture

Dr. S. W. Johnston, Vicksburg: No fracture should be put in a permanent splint until apposition has been demonstrated by the Roentgen ray. When accurate alignment cannot be secured by the usual methods, an incision should be made and a plating done. All compound fractures should be treated by the "open" method.

The Need of General Information on Infant-Feeding

Dr. R. N. Whitfield, Florence: The average physician says that he is too busy to spare the time necessary to perfect himself in the details of infant-feeding. One reason is that so much of his time is taken up in treating the conditions caused by improper feeding of infants. Another is that average milk-production is faulty. Milk laboratories are necessary—to get them we need cooperation among physicians and money. A clean dairy, a trained nurse and a couple of delivery-boys would supply our average town, and the nurse would have time to spare in which she might visit the homes of the poor where infants are being artificially fed.

Convulsions in Infancy and Childhood

Dr. A. W. McNeal, Ruleville: The most common cause is toxemia from intestinal disturbances. Rachitis has not been a factor in my practice.

Chorea

Dr. S. A. Majure, Dixon: Arsenic has given me the best results. General tonics are indicated and rest is essential. I have never seen a case in a negro.

Infantile Paralysis

Dr. J. C. McNair, Fayette: We had nineteen cases of infantile paralysis in Jefferson County in 1911. No more than two cases were within 5 miles of each other. My first case showed high temperature and rigidity of muscles, especially of the back and lower extremities. In another, the only fatal case, there was involvement of the respiratory muscles. In one there was loss of function of both lower limbs, the mother not thinking it necessary to call in a physician until she found that her child could not walk. The symptoms preceding the paralysis are not the same in all cases; they may be so insignificant as to be disregarded.

Quinin Amaurosis

Dr. W. M. Biggs, Rome: The patients in the cases which I report were aged, respectively, 2, 4, 6 and 4 years. The first three were brothers. The first received 2 grains every three hours for three days and then 4 grains every hour for a day; the second 6 grains every four hours for a day; the third 8 grains every four hours for a day and then 10 grains *of quinin with urea hypodermatically. The fourth was given* 40 grains of quinin and urea hypodermatically in two doses, six hours apart.

DISCUSSION

Dr. E. C. Parker, Gulfport: I should like to know if Dr. Biggs had his *quinin thoroughly examined to see* whether or not there were any impurities in it.

Dr. A. W. McNeal, Ruleville: There was recently a case of quinin amaurosis in my settlement. It resulted from the administration of something like 8 grains at four-hour intervals. That treatment was kept up for a day and eight hours, and the woman became totally blind. The quinin was discontinued and Fowler's solution begun in that case. The patient remained partially blind for something like a week after withdrawal of the quinin, but finally regained complete sight.

Rabies

Dr. F. M. Ranck, A. and M. College: Rabies may last from three to thirteen days and is most always fatal. It is not advisable to kill suspicious animals if they may be kept under observation. In the treatment of the wound, antiseptics and caustics are recommended. Bier's ligature is sometimes helpful.

1. **Tuberculous Infection.**—Healthy animals were killed by Findlay at short intervals varying between four and ten days, after the introduction of an exceedingly virulent culture (three weeks old) of tubercle bacillus and, with one exception (when the dose was 10 mg.), each capsule contained 5 mg. Emulsions of one lung and all the mesenteric glands from each case were made and introduced intraperitoneally through a small abdominal wound in *rabbits*, which were used for the secondary inoculations. Three of the animals inoculated with an emulsion of lung died too soon to give the disease time to develop, but in all the others ample time was allowed. In two of the animals inoculated with mesenteric glands, tuberculosis developed, thus showing that living tubercle bacilli had migrated to the mesenteric glands, but in not one instance were living bacilli demonstrated in the lungs by animal experiment. Both of the above mentioned infected animals had lived for a period of fifty-three days, and yet the disease was slight. It consisted of small tubercles situated chiefly in the omentum, but also in the mesentery and diaphragm, and apparently spreading by the lymphatics, the disease had infected the pleural cavities, several small subpleural nodules being visible. Films of the nodules revealed very scanty tubercle bacilli.

In one rabbit inoculated intraperitoneally with a very minute dose of the same culture as was used in the primary experiments, death occurred at the end of three days, when the peritoneum was found studded with minute tubercles containing abundant tubercle bacilli. In the inhalation experiments with the same type of organism, but another culture, the lungs were absolutely solid within thirty days. This *very different picture, Findlay says, would seem to show that* tubercle bacilli in their passage through the intestinal mucosa diminish considerably in virulence, but, the fact remains, that living tubercle bacilli can pass through the apparently healthy mucosa and reach the mesenteric glands within a period of six days, but such is *not of very frequent occurrence.*

In the second series of experiments the bacilli were introduced in greater quantity (10 mg.) after the animal had recovered from an intestinal catarrh induced by an infusion of senna leaves. In only one case out of five were living tubercle bacilli demonstrated in the mesenteric glands, but in not one instance were they shown to have reached the lungs within a matter of six days.

In a third series of experiments the animals were kept alive a sufficient time for the disease to develop. The dose of the culture varied between 10 and 20 mg. and was administered in a gelatin capsule with the stomach-tube. The majority of the animals (87 per cent.) which lived forty-six days or longer developed tuberculosis. In all the positive cases the gastro-intestinal tract presented lesions visible to the naked eye, and, with one exception, where undoubtedly insufflation had occurred, the intestinal foci were the most extensive. The appendix and adenoid patch at the ileocecal valve invariably, and in the earliest cases these parts alone, were the seat of the mischief. In one experiment, however, of only forty-six days' duration the cecum was in addition studded throughout with small nodules, and the mesenteric glands were extensively involved, presenting numerous caseous foci. In the majority of the positive experiments the mesenteric glands were also affected, and in those rabbits which had survived fifty days or longer infection of the *Peyer's patches was found, and in those killed seventy days* or more after inoculation an occasional nodule was encountered in the lungs. In no case was the spleen observed to be the seat of tuberculosis. These experiments prove that rabbits can be infected by feeding with tuberculous material. *In every instance the most extensive mischief was situated* locally in the intestine, and thus they lend absolutely no support to the idea that primary tuberculosis of any organ other than the bowel, can arise from bacilli which have gained admission by the intestinal route.

Of seventeen rabbits with diarrhea infected experimentally which lived longer than nineteen days, fourteen, that is, 82 per cent., developed tuberculosis, and all those that survived at least thirty days, that is, 100 per cent., showed definite infection of the gastro-intestinal tract. As in the healthy animals the earliest lesions were situated in the appendix and lymphoid area at the ileocecal valve in the form of small whitish nodules about the size of a pinhead lying immediately under the peritoneal coat. When the animals had lived for at least forty-one days the mesenteric glands invariably presented caseous foci, and the cecum and *lungs were as a rule the seat of tuberculosis. It is thus* seen that in the animals which had previously suffered from enteritis the lesions were on the whole similarly distributed to those occurring in rabbits not so affected.

Findlay also found that healthy rabbits may be infected by the ingestion of large amounts of the human tubercle bacillus. Rabbits just recovered from intestinal catarrh constantly, and within a much shorter period, develop tuberculosis after the ingestion of human tubercle bacilli. With the human type of organism a local intestinal lesion is not *always present, and when present is slight in comparison* with the diseased foci in the mesenteric glands or lungs.

Apparently primary pulmonary tuberculosis can be caused in rabbits by the ingestion of large amounts of human tubercle bacilli.

Findlay believes that the best means of combating the spread of bovine infection in childhood is in the avoidance of everything likely to cause intestinal catarrh, and in the sterilization of milk intended for the use of infants and children.

2. **Sprengel's Deformity.**—As a result of the study of 19 cases Neuhof concludes that congenital elevation of the scapula occurs in a familial form; unilateral and bilateral congenital elevation of the scapula are varieties of one affection. The deformity of the scapula and the defects in the trapezius (as well as other coexisting anomalies) are parts of a more general fault in development, i. e., Sprengel's deformity is a manifestation of atavism when it prevails in a familial form. It is probably a manifestation of atavism when it occurs in isolated instances. Neuhof is convinced that if sought for, more instances of congenital elevation of the scapula of familial type will in all probability be found.

5. **Spinal Anesthesia in Pelvic Surgery.**—Spinal anesthesia even in expert hands, according to Anspach will have a higher immediate mortality as a routine anesthetic than ether, chloroform or nitrous oxid. It has no postoperative mortality or morbidity, and in this respect is superior to ether, chloroform and infiltration anesthesia, but it is not superior in this respect to nitrous oxid and oxygen. It is more troublesome to the surgeon than ether, chloroform or nitrous oxid and oxygen anesthesia. Anspach advises that spinal anesthesia should not be used unless the surgeon has familiarized himself thoroughly with all the details of the technic; he also should be aware, fully, of the complications which may arise, and be ready to meet them at a moment's notice. Well given it is the best form of anesthesia in selected cases, but it should be reserved for those operations in which the dangers of general anesthesia are increased, or in which nitrous oxid and oxygen and local anesthesia are unsuitable or unsatisfactory.

7. **Necrosis of Uterine Fibroma.**—The best treatment of necrotic fibroma, Shoemaker says, is preventive. That is, the removal of all large or growing tumors, or those which cause symptoms, before they become necrotic. The Roentgen ray is a temporizing expedient which will result in many deaths, either from overlooked malignancy, or from late complications. Whenever possible, Shoemaker states, the tumors should be removed by the vagina, leaving the uterus if possible, and leaving the ovaries if hysterectomy is done. The actual cautery is a valuable help in the vaginal cases for after-treatment of the tumor site. The mortality will depend on the degree of infection present when the operation is performed, and should be lowest in those treated by the vagina.

30 *Murphy Button Almost Entirely Digested Within Four Years. O. Kiliani, New York.

30. **Murphy Button Almost Entirely Digested.**—In 1904 a posterior gastro-enterostomy by means of a Murphy button was done by Kiliani. After that, the patient was perfectly well for five months, then he began to suffer from the same symptoms as before operation, namely, vomiting and epigastric pain, but never as severe. Before operation he often vomited blood, but never after that. During all these four years whenever he got an attack of pain and vomiting, he would stop work for a week or so, until it subsided, and then resume his work.

His history before the last operation was as follows: Lately attacks have become more severe, and from four to five weeks he has had continual pain in the epigastrium, with exacerbation of very agonizing pain, coming on especially at night, not after meals. He thinks pain is relieved by eating, but it returns with increased force, one to one and a half hours after meals. Pain radiates to back and is very intense there, chiefly on left side, also shoots to region of heart, never to shoulder or downward. Soon after the pain comes he has to vomit, usually one to one and a half hours after meals. Often vomits large quantities; sometimes he vomits food which he took the day before. He has not vomited blood, appetite good, but afraid to eat on account of pain and vomiting. Has lost about 10 pounds. Bowels constipated, has to take cathartics. Stool usually hard and black. Urination normal. The patient says he did not pass the Murphy button which was used for his gastro-enterostomy, four years ago. Just before operation a roentgenogram was made of the umbilical region. No button was seen. Another was made of the region above this, which showed a shadow suggesting Murphy button—not as clear, though, as shadow of a metal substance should be.

In 1909 Kiliani operated again; gastrostomy then done. Without much difficulty a wire spiral spring from Murphy button was withdrawn from the pylorus. The latter was patent, and admitted tip of index finger. The remainder of stomach was then palpated, but nothing else abnormal found. The old gastro-enterostomy was carefully felt for with one finger inside of the stomach and the other one outside, but no opening could be found. Apparently it had closed entirely.

41 Guaiacol Poisoning by Absorption. Report of Case. L. A. Secton, New York.

36. **Malaria in Infants.**—If seen during the early part of the paroxysm Weston gives a hot mustard bath, applies an ice cap to the head, and if the infant is having convulsions gives bromid of soda and antipyrin also. If the infant is in this stage, frequent tepid spongings give great relief. The bowels should be promptly and freely opened by the use of frequent small doses of calomel. Other medicinal treatment consists in the administration of quinin, preferably bisulphate in aqueous solution. The stomach of infants suffering from malaria is almost invariably very irritable, and it is therefore important that quinin should be given only at those times when it will be most effective in destroying the parasites. Weston advises that in benign attacks no quinin be administered for at least three hours after the temperature becomes normal. Then administer 2 grains bisulphate in aqueous solution every two hours day and night for twenty-four hours, then 2 grains of the solution every four hours for twenty-four hours, then 3 grains morning and evening for three weeks. It absorbs more readily when the stomach is empty. If difficulty is found in retaining the bisulphate, euquinin or the tannate may be tried. In pernicious malaria quinin hypodermically is the only method to be relied on.

The best salt of quinin for injection in Weston's opinion is the bimuriate. The tablets of bimuriate of quinin and urea are convenient and reliable. The 3-grain tablets contain about 2½ grains of the quinin salt. The tablet should be dissolved in distilled water or merely sterilized water. The needle and syringe must be sterile and the skin sterilized. The solution is then injected deep into the muscles. This procedure may be repeated every six hours. Finally the rectal administration of quinin may be resorted to. Here the bimuriate in doses three times as large as would be given by the mouth or intramuscularly should be given in 2 ounces of warm water. This injection should be given high up in the rectum. It is well to add 5 drops of tincture of opium to the solution to prevent tenesmus and aid retention.

49. **Green Operating Room.**—The discomfort Sherman has had in the present-day white operating rooms led him to suggest dark floors and wainscots in these rooms, so that the operator who looks up from a wound shall not encounter a glare of light and find his eyes useless for a moment, as he looks back into the less illuminated wound. The color scheme, it seemed to him should start from the red of the blood and of the tissues, therefore he advised that green, the complementary color to red, should be chosen for the color of the floor and wainscot. The particular shade of green to be selected was that which was complementary to hemoglobin, and it was found to be the green of the spinach leaf. A room painted in this way, the floor, and the walls for six feet from the floor, a bright spinach green, and all about a glazed white, was matched for use against a room painted a glazed white—floor, walls and ceiling—in the operating pavilion at St. Luke's Hospital. Sherman says that no one who could get into the green room to do an operation ever went into the white room. Above the level of the six-foot green wainscot is white encaustic tiling to the ceiling, and the ceiling itself is a bright buff. Sheets, towelings and gowns and the coverings for the instrument tables are of black.

60. **Iodin Specific Germicide in Respiratory Affections.**—In the treatment of respiratory affections Blum has employed with equally beneficial results hydriodic acid and the iodids of potassium, ammonium, sodium and strontium. The syrup of hydriodic acid, he says, is especially applicable for adults with sensitive digestion and for children. Apart from this consideration the desideratum is to give sufficient iodid to definitely affect the respiratory secretion without causing unpleasant and unfavorable symptoms—coryza, lacrimation and digestive disturbance.

63. **Persistent Hereditary Edema of Legs.**—*Phillip's first* patient, male, aged 40, complained of severe cough, which was due to a subacute bronchitis, and this cleared up quickly under treatment. In the course of the physical examination it was discovered that there was a well-marked painless edema of the left leg, extending from the knee downward. The edema was not so well marked over the foot and ankle, because it was reduced by wearing his shoe. On further questioning, the patient stated that this condition had been present from the first year of his life. It had never caused him any great inconvenience, except that at times his affected leg would become red, swollen, hot and very tender. At these times he would feel very ill and feverish, and there would be some disturbance of his stomach. He could assign no cause for these acute attacks other than at times it would follow slight injuries. This condition would subside in the course of three or four days. These attacks began at the age of 10 years, and occurred once or twice a year until the past eight years, when they have been growing much less

frequent. His right leg was unaffected and his left leg was normal above the knee. With the exception of this condition there was nothing abnormal found on physical examination.

The second patient, a boy, aged 6 years, son of the first patient, showed a condition similar to that seen in his father, except that the right leg was affected. The general character of the swelling was the same except that there was greater edema over the dorsum of the foot because he had been going about in his bare feet all summer. His mother had first noticed the swelling of his leg when he was 4 months old, and it had gradually increased and remained since that time. The boy had suffered no inconvenience from his enlarged leg until the time he was first seen. In October, 1913, after a slight scratch on his right foot, he developed in a few hours a red brawny swelling extending to the knee. This was very painful and tender to the touch. The upper border of the swelling was raised and sharply defined. His temperature rose to 104 F. and the patient had severe nausea and vomiting. The physician who saw him at that time thought that the condition was one of septic infection and advised operative procedures, but the mother refused consent, because she knew that his father suffered similar attacks and quickly recovered. That her judgment was correct was shown by the fact that the pain, redness and swelling disappeared, and the temperature returned to normal three days later. Since then he has had no more acute attacks.

126 Ocular Manifestations of Sinus Disease. C. W. Gosney, Kansas City.

125. **Removal of Goiter**—A double four-pronged forceps is used by Outland to make traction on the lobe selected for enucleation. The superior pole is thus brought into easy operative reach often without the division of the sternomastoid muscle. An aneurysm needle is then forced under the superior thyroid vessels through the substance of the gland and ligated. The inferior vessels are treated in the same fashion, after dissecting the gland from above and freeing it from the capsule posteriorly.

137. **Salvarsan Treatment of Brain Tumor Symptoms Dependent on Syphilis.**—Three cases are cited by Collins to call attention to the importance of making a Wassermann examination in all cases in which there is suspicion of brain tumor. The prompt way they yielded to treatment is emphasized to testify to the value of salvarsan in the treatment of syphilitic nervous disease.

143. **Tropical Malaria**—To fight malarial fever, Braddock says, sanitation is as necessary as mosquito prevention, and this means good water and protection from the elements Everywhere in the tropics as far as possible always use mosquito curtains, as they are absolutely necessary for comfort and health. He says that if you obey the laws of the jungle you can travel with comparative security in any jungle in the world. Sleep as high from the ground as possible, drink distilled or boiled water, use mosquito curtains, give prophylactic doses of quinin, and always cut away the jungle as far as possible in the camping place. Braddock lays much stress on cutting the jungle back, because just in proportion as the jungle is cut away and the sun let in around mines, canals and railroads, cities and towns, so will the malarial rate decrease. Then if the mosquitoes are also destroyed and the people sleep as high from the ground as possible and have a good supply of rain or distilled water for drinking purposes, or artesian well water, with good sanitation, wonderful results can be accomplished.

Braddock believes that the mosquito is not the only carrier of malaria, but that, differing from yellow fever, malaria is carried by water and soil, and that the mosquito when not infected by a person suffering from malaria gets it from the water in which it was born. His observations have been made personally in Cuba and Hayti, and in Siam, French Indo-China, Siamese Malaya, Federated Malay States, and along the eastern Burmese frontier, and in Ceylon and Egypt.

159 *Variability of Certain Strains of Dysentery Bacilli as Studied by Single-Cell Method. M. A. Barber.

150. **Inoculation of Monkeys.**—Ashburn and his co-workers found that fresh vesicle contents from a case of human variola is capable, when inoculated into abrasions or scarifications on non-vaccinated monkeys, of producing variola inoculata in those monkeys, the disease being marked by fever and by primary and secondary lesions. Such vesicle contents kept at ice-chest temperature for twenty-three days loses most of its virulence, but may still, in a proportion of instances, produce a mild and atypical variola inoculata, which in turn and in further modified form may be passed to other monkeys. Active and fresh vesicle contents inoculated on vaccinated monkeys may produce a fever closely resembling that of variola inoculata in the monkey and a condition permitting of interpretation as variola sine exanthemate in the monkey. Small-pox scabs or disks from man or monkey possess but a low degree of virulence, or very quickly lose their virulence. When inoculation of such scabs does result in the production of infection this may be manifested only locally at the site of inoculation. The authors restate their hypothesis that small-pox is due to a dual and divisible virus, one part of which is the cause of vaccinia and the pock stage of small-pox, the other part being necessary for the production of the highly contagious febrile, general disease with an initial stage and preliminary rashes.

159. **Dysentery Bacilli.**—From a culture of bacillus dysenteria, Flexner type, derived from a single-cell, 3 series of single-cell isolations were made by Barber at intervals of about five months. The first series gave 5 maltose-fermenting variants out of 21 isolations; the second, 5 out of 60; the third, 1 out of 123. The other single-cell cultures as well as the parent culture render maltose alkaline. The non-fermenting type produces secondary colonies consisting of normal and involution cells, either of which may develop acid or alkaline producing cultures. An ordinary transfer from a secondary colony, including many cells of both sorts, gives an acid-forming culture. Selection from the acid-producing type failed to produce any but similar types, and selection from the alkaline-producing type gave only alkaline, provided secondary colonies were not chosen. Mixed cultures, consisting of an equal number of cells of each type, showed that the two types may exist side by side through from 10 to 15 daily transfers, but with a tendency for the acid to outstrip the alkaline. Transfer to maltose broth gave no increase in the acid-producing power except in old cultures. Growth in various substances other than maltose failed to alter materially the characteristics of the two types. In a specific serum, the two types showed approximately the same agglutination. A permanent new race, characterized by morphologic peculiarities, was obtained by the selection of an aberrant cell from a culture of dysentery of the Shiga-Kruse type.

167. **Malaria During First Three Months of Life.**—In children during the first three months of life, the first clinical manifestation of malaria, Booth says, is usually the finding of the child asleep with a high temperature. It may

or may not have been cross or irritable, but usually, if it has been the fact, it has been overlooked by the family. On waking him, he is exceedingly cross and irritable, jumping from the slightest noise; he is usually very much nauseated, the stomach rejects everything as soon as it reaches it. The temperature rises rapidly, the pulse is at first full and strong, but as the temperature rises it becomes weak and thready; the skin is dry and hot, feeling almost parched to the touch; the respiration becomes rapid and shallow; the patient is constantly moving his hands and feet, rolling his head from side to side if old enough, and if the fever exceeds 103 F. there are usually convulsions, followed by coma. Owing to the unstable equilibrium of the nervous system, all of the nervous symptoms of a malarial attack are exaggerated, and when the infant begins having convulsions, or goes into a state of coma, unless the fever is speedily reduced and the nervous system fortified, death results in a short time. When the infant has been tided over the paroxysm and the immediate danger of death is passed, it is usually found very much debilitated. The child's appetite is now variable; sometimes the stomach is still irritable and easily nauseated, the stools become frequent, watery and have an offensive odor; emaciation is rapid, resulting if untreated, in a speedy death. A microscopic examination of the blood will almost always reveal the malarial plasmodium. If not, the apparent leukocytosis in a case of this kind is almost pathognomonic.

Sometimes, instead of the onset occurring while the child is asleep, the first manifestation of the attack is a convulsion, which comes on without any warning, but after its onset the attack presents practically the same clinical symptoms as already described. Booth has seen these attacks occur in children only two weeks old. They occur most frequently in the late summer, being rare after cooler weather sets in. The treatment is outlined as follows: Cold baths to reduce the temperature, if practicable, and if not, then hot ones. Small doses of heroin and atropin, or morphin and atropin to control the convulsions and equalize the circulation. A good mercurial purgative followed by plenty of castor oil as hot as can be given; also plenty of quinin. After the acute symptoms have subsided, iron in such forms as to be easily assimilated, with essence of pepsin in appropriate doses will cause a quick recovery from the emaciated condition.

168. **Factors in Prevention of Malaria.**—There is one mighty weapon in the campaign against malaria which Deaderick says has been all but neglected in past campaigns, excepting a recent one in California, and that is education. The public should be made familiar with the etiology of the disease, practical preventive measures, and especially with the public health significance of the latent or carrier stage. Many adult inhabitants of malarial sections of this country could not be educated up to practical malaria prophylaxis even with concentrated effort throughout a long life-time, but by devoting careful attention to their children and to their children's children a generation of malaria fighters would be bred.

169. **Quinin-Fast Malarial Parasites.**—When a man is suffering from a malarial infection which from time to time develops into malarial fever Carter points out that the parasites must exist in him during the interval between the attacks although not in sufficient numbers, or in such form as to produce an attack of fever. When enough asexual forms are produced from them to provoke systemic reaction, the relapse is produced. During the interval there seems no evidence that they, the parasites, exist in any other form than as we usually know them, or in any other tissue except the hematocytes, although of course, both are possibilities. The increase of asexual forms should come, then, from the proliferation of the parasites in the ordinary way, and the daughter-parasites should, more or less, partake of the characteristics, original and acquired, of those from which they spring.

In relapsing malaria quinin may be given during the attack sufficient to cure it and to destroy the greater part of the asexual parasites, so that there are not enough left to keep up the attack; it may be given between the attacks in the same doses, and continued some time without preventing the relapse—that is, without killing all the parasites, enough escaping to proliferate later and produce the relapse with an abundance of asexual forms in the cutaneous circulation. The great bulk of the parasites in such relapses are destroyed by ordinary full doses of quinin, but a small number (too small to produce malarial fever and generally too small for asexual forms to be found in the blood) are not killed by them. These, Carter says, are the so-called "quinin-fast" parasites. Two hypotheses are advanced by Carter: 1. The parasites that survive are less susceptible than normal to the action of quinin. 2. They are less accessible to it than normal.

173. **Raw Surfaces in Peritoneum.**—It is essential that all raw surfaces in the peritoneum be covered or protected. The best method is to bring the edges together with a running suture, and if time permits, to use a second suture to reenforce and cover over the first. The use of sutures is not applicable to over 50 per cent. of cases, and in those cases in which sutures cannot be used, Burch says, preference should be given to peritoneal or omental grafts. In cases of general peritonitis, associated with raw surfaces, time is an important element, and a finished technic is unwise. In this class of cases Burch uses warmed camphorated oil, 1 per cent. The method of Richardson should be used in those cases with raw surfaces on the intestine, provided of course, the intestine has a mesentary sufficiently long. Sumners' method of using the sigmoid to cover raw surfaces in the pelvis, Burch says, is indicated in a small proportion of cases. All oozing surfaces should be touched with alcohol or the cautery to prevent infection. Sterile vaseline has an inhibitory influence on adhesions, and if time does not permit of other measures, it should be used.

181. **New Technic for Total Hysterectomy.**—In the operation described by Scott, the patient is placed on the edge of the table, as if for lithotomy or vaginal hysterectomy, but instead of the limbs being fastened to the upright leg holders at the corners of the table in a position in which the thighs are flexed on the abdomen, the limbs are held so that the thighs are extended and widely abducted. Two operators are required, and the one who operates through the vagina either sits or stands, according to whether the abdominal operator desires the horizontal or the elevated position. Both operators begin simultaneously. The vaginal operator uses no knife at all, but surrounds the cervix with a cautery incision through the vaginal wall, made not far above the point of the cervix on the anterior side, to loosen the cervix from the bladder attachment. In the meantime, the abdominal operator has incised the abdominal wall, separated any adhesions to the uterus and appendages, packed off the intestines, ligated and severed the ovarian vessels and round ligaments and separated the bladder from the uterus, carefully approaching the cautery of the vaginal operation. By cooperation of the two the operation is carried to its termination in the manner described by Scott in detail.

British Medical Journal, London

May 2, I, No. 2783, pp. 949-1000

1 *Diagnosis and Treatment of Cerebrospinal Syphilis. P. Stewart.
2 Clinical Manifestations of Congenital Syphilis. H. Armstrong.
3 Clinical Importance of Cerebrospinal Fluid. W. Boyd.
4 *Meningitis in Children. W. M. Smith.

1. **Treatment of Cerebrospinal Syphilis.**—Improvement in the condition of the cerebrospinal fluid is a useful index of arrest of the disease, but, Stewart says, it must be remembered that, in general paralysis at least, the cell-count in the fluid may go down without any corresponding improvement in the mental symptoms. This is readily understood when one bears in mind that, even if the disease process be arrested, those nerve-cells and nerve-fibers which have been already destroyed, remain destroyed and cannot be regenerated. It is therefore of importance to select only those cases of general paralysis which are in the early or toxic stage of the disease, before the cortex has become profoundly degenerated. The earlier the disease is recognized, the better are the prospects of improvement. Advanced cases with profound cortical degeneration are totally unsuitable. The most thorough method of attacking general paralysis would be to administer remedies concurrently by all three routes—intravenously, intraspinally and intracranially. It is too early to claim that we yet possess a cure for tabes or general paralysis, but Stewart believes that in suitable cases, much can be done to arrest both diseases. Whether such periods of arrest are permanent, time alone will show.

4. **Meningitis in Children.**—In epidemic meningococcal meningitis the results of the intraspinous injection of a suitable serum, Smith believes, have justified the treatment, and the mortality has been reduced from 70 to about 20 per cent., and, indeed, might be lower were all the cases treated within the first two or three days. A large injection of Flexner's serum—about 20 c.c. even in a child—is given for two or three days, and repeated later if rapid improvement does not take place. In chronic cases with persistent headache and vomiting the injection of the serum is likely to be attended with satisfactory results. In the other forms of meningitis intraspinous injection of a serum is worth trying when the case is seen early, but the results so far are by no means satisfactory. In the chronic forms of meningitis due to syphilis, treatment is now being introduced in which the serum of a patient after treatment with salvarsan is injected into the spinal theca after the withdrawal of an amount of cerebrospinal fluid equal to that which is to be injected. Repeated lumbar puncture, in the hope of minimizing the evil effect of pressure, is indicated, especially in those cases which run a protracted course. In serous meningitis and meningism, lumbar puncture is generally attended with excellent results.

Hexamethylenamin is the drug which is most likely to be useful. It appears in the cerebrospinal fluid, and is said to have an inhibitory effect on the growth of organisms. It may be given in 10 grain doses every four hours, even in young children. Bromid and chloral, trional or morphin may be given as necessary for relieving headache and inducing sleep.

General treatment runs on the ordinary lines—a water bed, the child being moved as little as possible, tepid sponging, and the usual attention to the bowels. Persistent sickness in the chronic cases may be alleviated by washing out the stomach, and, if the vomiting persists, feeding with the nasal tube should be tried. The act of swallowing in some cases seems to cause a tendency to vomit, whereas the nasal tube passed below the pharynx has not this effect. During convalescence, so long as the tongue is clean and the bowels regular, a liberal diet should be given.

16 *Pain after Operation for Internal Hemorrhoids, and Its Prevention. P. L. Mummery.
17 *Early Detection of Diabetes by Simple Method of Estimation of Blood-Sugar. O. Kraus.

15. **Acute Lobar Collapse of Lung.**—Inaction of the muscles of respiration according to Tidy and Phillips is a cause of acute lobar collapse. Blockage of the bronchioles from capillary bronchitis may possibly have a similar result. The authors suggest that lobar collapse may explain cases of pleural effusion without corresponding displacement of the mediastinum and heart. In a case described, acute pleurisy occurred without changes in the lung. Inhibition of the muscles of respiration resulted in acute lobar collapse.

16. **Prevention of Pain after Operation for Hemorrhoids.**—Pain following operations for piles, Mummery says, can be prevented by applying the same principles that have enabled surgeons to avoid pain resulting from operation wounds in other parts of the [illegible] If a wound is made with no bruising or tearing of the tissues, under aseptic conditions, through clean tissues, and is kept aseptic and at rest, pain, except of a very slight and transient character, does not result. The anal region is no exception to this rule, and, given the same conditions, after-pain will be equally absent from operations in this region.

Careful attention to the details of aseptic technic must be observed in order to obtain success. The patient must be so prepared for operation that the rectum is quite empty and will remain so for some days. This is essential. The rectum and the whole of the field of operation must be washed out thoroughly with soap and water, and afterward with a suitable antiseptic, until the surgeon is satisfied that the area of operation is surgically clean. The sphincter should not be stretched or damaged in any way, and the patient must therefore be anesthetized thoroughly and deeply or the sphincter will be in a condition of spasm which will render it impossible for the surgeon to reach the piles properly. The operation must be carried out with as little damage to the tissues as possible. Pressure forceps should not be applied to tissues which are not going to be removed; the mucous membrane or skin at the anal margin must not be included in ligatures, and the number of ligatures applied for the control of hemorrhage must be reduced to the smallest possible number. After the completion of the operation the wound must be bathed with some suitable antiseptic, the best, in Mummery's opinion, being 1 in 40 phenol. Lastly, some form of dressing must be applied which will prevent infection of the wound. For this purpose Mummery has found sterilized vaseline to be the best, and the lower part of the rectum may be filled with this.

For the last ten years, he has been operating for piles on these lines, using the ligature operation in all but a few special cases, and has found that postoperative pain is not more severe or frequent than after operations for hernia or varicose veins.

17. **Early Detection of Diabetes.**—The analysis of blood-sugar is carried out by Kraus in the following manner: The pulp of the middle finger is thoroughly cleansed with ether and alcohol and a prick made with a Francke's needle, and about fifteen drops of blood are dripped into a special small glass receptacle. Then by means of a capillary pipette 1 c.c. is measured into a small beaker. The liquid in the beaker is cautiously heated, whilst stirring it up, until it begins to turn turbid. Then 4 to 5 drops of 10 per cent. ferrum oxydatum dialysatum duplex are added, and subsequently a few drops of a saturated watery solution of potassium sulphate, with constant soft boiling and stirring. All of a sudden the albumin will accumulate on the surface, while the liquid beneath will become absolutely clear. This liquid will hold all the *sugar contained in* 1 c.c. of blood. Two *gm. of sulphate of* copper are exactly weighed and dissolved in about 100 c.c. of water and cooled down. Then 400 gm. of sulphocyanate of potassium, 12 gm. of ignited carbonate of sodium, and 24 gm. of citrate of sodium are dissolved with the aid of heat in about 600 c.c. of distilled water and filtered. It is then cooled down and the copper solution added by slowly pouring it into the other solution with constant stirring. Five c.c. of a solution of 5 per cent. of ferrocyanid of potassium are now added and the whole is diluted with distilled water to exactly 1,000 c.c.; 0.165 gm. of pure glucose is dissolved in a flask that holds 100 c.c. and is provided with a mark. Then a double tube is inserted and the bottle, neck downward, is put into communication with a special buret by means of a rubber tube. This buret holds 1 c.c. divided into 100 subdivisions. Twenty-five c.c. of the cuprous solution, with 25 additional c.c. of distilled water, are measured into a beaker and heated; then the sugar solution, still boiling, is poured into the beaker, at first rapidly, finally drop by drop.

Kraus generally uses 3.35 to 3.36 c.c. to reduce 25 c.c. of the cuprous solution. The reaction is complete when the color changes from light blue to faint canary. The titration of the blood-sugar takes place on the same principle—25 c.c. of the standard solution are added to the blood filtrate and heated, and the end-point will be obtained by addition of the sugar solution. The difference between the result of the test titration and the amount of sugar solution that it was necessary to add to the blood filtrate, when multiplied by 0.165, gives the percentage of sugar in the blood.

18. **Syphilis and Insanity.**—Savage's experience, both in hospital and in private practice, is that syphilis is the dominant, if not the sole, cause of general paralysis of the insane. Syphilis may be a cause of congenital mental defect; it may be a cause of preventing healthy development of the brain; or it may interfere with development by the senses, and may thus lead to defective education. It may give rise to convulsions, which may either become established, as epilepsy, or may lead to mental weakness. It may also affect the moral development; and patients with a syphilitic inheritance have, in Savage's experience, not infrequently been morally defective in one way or another, and incapable of recognizing their social duties. Syphilis may cause hypochondriacal feelings, and the presence of stigmata may make the patient believe that he is a suspect, and may thus give rise to delusions of suspicion, melancholia and suicide. Congenital syphilis is almost certainly the cause of adolescent general paralysis. Ordinary general paralysis, locomotor ataxy with mental symptoms, are associated, in nearly all cases in Savage's experience, with a history of syphilis. Besides this, there are many forms of dementia depending on arterial degeneration which may produce general brain decay, or local troubles, such as softening or apoplectic seizures.

19. **Digitalis in Heart Disease.**—That digitalis is not efficient in all disease and disorders of the heart is emphasized by Powell. In acute injuries, such as rupture of the aortic valves, in such acute affections as pericarditis, endocarditis, myocarditis, it is of little or only of quite subordinate value. In chronic disease of the myocardium, of syphilitic, alcoholic or coronary origin, the use of digitalis is of secondary importance, and is often distinctly contra-indicated. It is in chronic valvular disease with failing power of ventricles that digitalis and, in a less degree, the class of drugs which it represents, are especially indicated; in fatigue of heart after acute disease or strain, it is also of great value.

20. **Glycosuria and Disease of Pancreas.**—The first essential, says Cammidge, in the treatment of all cases of glycosuria, is that the diet should be adjusted as accurately as possible to the metabolic powers of the patient, so that, while sufficient food is taken and absorbed to meet the requirements of the body, all unnecessary strain on the defective functions is avoided. Each patient is a law unto himself, as to the kind and quantity of food that can efficiently be dealt with and is best tolerated. One cannot argue from one case to another, or lay down rules that will be generally applicable. Diabetes is essentially a disturbance of the chemistry of the body, in which metabolism of carbohydrates, fats and proteins may all be involved, and to treat patients satisfactorily, one must ascertain their powers of dealing with each of these substances. The earlier in the course of the disease the treatment can be commenced, the easier will be the task and the more satisfactory the results.

31. **Pancreatic Hemorrhage.**—The interesting features of this case are cited by Elder and Daniels to be: the sudden onset of the acute symptoms after an interperiod of general malaise in a man previously healthy; the absence of any indication in the urine of pancreatic disease; the peculiar rash which appeared on the abdomen; the comparatively peaceful interval; and the rapid onset again of acute symptoms; there was no indication at the operation of fat necrosis, such as is usually described in such cases.

It seems to the authors that early operation in these pancreatic hemorrhages holds out the prospect of a much smaller mortality in this generally fatal complaint.

39 *Improved Technic for Correction of Club-Foot. (Tarsectomie pour pied-bot.) C. Willems.
40 *Cancer of the Prostate. P. J. Freyer.
41 Plexiform Neuroma. D. Taddei.

39. **Tarsectomy for Talipes.**—Willems cuts out the skin over the region as the first step, leaving a pear-shaped gap tapering to a point at the heel. Then he removes the astragalus; this corrects the equinus. Then he resects more or less of the calcaneum as needed, and slides the cuboid bone backward into the place of the astragalus and sutures the skin in a single linear suture. By this means the various factors of the deformity are corrected in turn, and the soft parts develop to form a false joint between the cuboid and the tibia, which restores approximately normal functioning to the foot. Almost all forms and degrees of talipes can be readily corrected by this technic, he says. He gives an illustrated description of it, adding that the linear scar and perfect functioning in the 200 cases in which he has applied the method justify its wide adoption.

40. **Cancer of the Prostate.**—Freyer states that he found malignant disease in 13.4 per cent. of the 1,276 cases of enlargement of the prostate in his private practice in the last eleven years. The symptoms are those of ordinary enlargement only that they have appeared and developed in the course of a few months instead of coming on gradually in a few years. This briefer course is very suspicious for cancer; still more if the patient has felt weak and languid, with little appetite, and if he has pains in the sacrum, loins or one or both thighs, along the urethra or in the perineum, and if he has pains in one or both buttocks when he sits down. The patient usually ascribes these pains to "rheumatism." His tongue may be glazed, red and dry, the urine pale and of low specific gravity. Hematuria is extremely rare with cancer of the prostate, and occurs usually only in the advanced stages. In exceptional cases there may be a few drops of blood passed before micturition or independently of it. Profuse hematuria is more a sign of simple adenomatous enlargement of the prostate. When the cancer develops in a previously enlarged adenomatous prostate, and the malignant growth is still confined within the capsule of the gland, the prospects for a complete cure by prostatectomy are favorable, as he shows by eight typical cases related. The article is in English but is not illustrated.

42 *The Mediastinal Syndrome; Two Cases. Creyx.

42. **The Mediastinal Syndrome.**—Creyx emphasizes the importance of treatment for syphilis when confronted by a chronic mediastinitis in an adult. In children the lower part of the mediastinum or the upper part may be involved when symptoms call attention to this region; the inflammation can generally be traced to lesions in the tracheo-bronchial lymph-nodes. In adults the upper portion alone is more liable to be affected, and the source of the trouble may be discovered in the aorta, esophagus, etc. But it may be the only localization of some infection, usually syphilis, and specific treatment may speedily cure the threatening syndrome. In one of the two cases described the chronic superior mediastinitis in a man of 56 proved to be the work of an aneurysm of the aorta in an old syphilitic. The aneurysm had compressed the superior vena cava and a main bronchus. In a second somewhat similar case the symptoms indicated compression of nerves instead of the vessels. Specific treatment will eliminate the syphilitic factor and may cure even when there are severe disturbances from compression of the recurrent nerve, bronchi or esophagus, with reflex tachycardia and spasmodic cough. The sympathetic nerve is usually spared and hence there are no pupil anomalies or vasomotor phenomena in the face.

45 Conditions in which It Is Necessary to Resect the Intestine in Operating for Hernia. E. Quénu and H. Constantini.

46 *Chronic Pancreatitis. (Les pancréatites non biliaires.) J. Walter-Sallis. *First part in XXXIII, No. 12.*

47 *Clinical and Experimental Study of Traumatic Backward Dislocation of the Knee. P. Hardouin. First part in XXXIII, No. 12.

46. **Chronic Non-Biliary Pancreatitis.**—Sallis states that he found only two cases of diabetes mellitus among 250 cases of chronic pancreatitis which he has compiled. On the other hand, he found glycosuria in 11 of 13 cases of syphilis of the pancreas. He noticed it also in a few cases of tuberculosis of the pancreas. The diagnosis of chronic non-biliary pancreatitis is based on a history of digestive disturbances with pains in the epigastric region and right hypochondrium, less frequently in the left; the rapid and considerable loss of flesh; the anemia which accompanies the emaciation; a slight suggestion of jaundice; fat in the stools; slight bulging above the umbilicus, and rigid rectus muscles. The head of the pancreas can be felt hard and knobby, possibly tender and tumefied. When the stomach is inflated, the tumor vanishes. Complications on the part of the bile ducts, intestines and pylorus are by no means rare, as they suffer from compression by the enlarged head of the pancreas. Sallis relates a number of such case-histories from his own experience and summarizes forty-four from the literature. He says in regard to treatment that a mere exploratory laparotomy may induce the retrogression of pancreatitis in its early stage. This has been done in nineteen cases and with success in all. In a farther advanced stage, thorough retropancreatic drainage has proved effectual in some cases, both for biliary and non-biliary pancreatitis. If the common bile duct is entirely occluded, the pancreas will have to be cut to release the duct from the bed of sclerous tissue in which it is being smothered. The chronically inflamed pancreas bleeds easily and profusely so that this pancreatotomy had better be done extremely cautiously with the actual cautery. As a rule the pancreas recuperates after an operation very slowly, two, three or nine months sometimes being required. He reports a case in which the symptoms of pancreatitis returned a month after the operation. The pancreas was drained and the patient had apparently entirely recovered, when the pancreas syndrome flared up anew for a few days but then subsided completely.

47. **Backward Dislocation of the Knee.**—Hardouin concludes his long study of this subject by giving full summaries of the seventy-eight cases he has found on record and one from his own experience. In ten cases it proved impossible to reduce the dislocation immediately after the accident. The reason for this was generally that the internal condyle of the femur had been forced through the muscle and fascia and was held firmly in the button-hole thus made. Factors preventing reduction can be suspected when the patella is held immovable against the external condyle, when considerable abduction of the leg on the thigh is possible, and when there is a round hollow in the skin at the interline of the joint. Expectant treatment when reduction at once was impossible gave but mediocre results in the one case in which it was applied. The leg was amputated in one case; resection in another gave good functional results. In seven cases the joint was opened to correct conditions with fine results in three and fair in two cases. Infectious complications followed in two. When the dislocation is of long standing and the patients have learned to get along with it, there is not much use in interfering. The longest interval after which reduction was possible by the ordinary technic was two weeks; Küster found it impossible in one case at the ninth and Reisinger at the seventh week. Hardouin discusses the treatment applicable to the various complications that may arise at the time or later, especially from functional insufficiency of the ligaments. In seven of the cases the dislocation had occurred years before; one man of 70 referred it to a fall at 9 months. In four in this group the deformity was pronounced but did not interfere with

the earning capacity. Another gradually regained the use of his leg after having been bed-ridden from it for two years. Another had to have the limb amputated. Another could use her leg without trouble by wearing a bandage to keep the bone from slipping sideways. The dislocation should be reduced as promptly as possible on account of the danger from compression of nerves and vessels. An almost certain sign of this type of luxation is the horizontal position of the patella with complete dislocation, and nearly horizontal in the incomplete form. This sign is most instructive when the leg is stretched or bent upward.

48 *Ovarian Treatment. (Lipoides homo-stimulants de l'ovaire et du corps jaune.) H. Iscovesco.
49 Technic for Suture of Severed Ureter. (Urétérorrhaphie dans les sections totales de l'urétère.) P. Sejournet.

48. **Ovarian Treatment.**—Iscovesco called attention in 1910 to the specific physiologic properties of lipoids which can be extracted from some of the organs with an internal secretion. These lipoids seem to act as chemical messengers inducing a kind of autoregulation of the functioning of certain organs. Some seem to stimulate the organ from which they are derived; others act on other organs. Repeated injection of the lipoid extracted from the organ of another individual of the same or another species induces hyperfunctioning and in time hypertrophy of the organ in question. He here reports experiments with the lipoid extracted from the ovary and corpus luteum. It is a homostimulator; that is, it acts mainly, if not exclusively, on the female internal genital organs. He gives some illustrations showing the way in which the ovaries and uterus of rabbits developed under its influence to twice or thrice the size of those in the controls. In 48 cases of painful dysmenorrhea he injected the extract on alternate days for two weeks before the menses, and all but 8 of the patients had no further pain thereafter; in 6 of the refractory cases the course was not complete. The organ therapy proved constantly effectual in 6 cases of amenorrhea and in a much larger number of cases of various disturbances from insufficient functioning of the ovaries. His extensive experience has demonstrated, he says, that injected lipoids do not induce phenomena of anaphylaxis. The aim being to exaggerate the normal functioning, treatment should be mild and gradual and long kept up. The lipoid used in his work was taken from sows, a kilogram of sow ovaries yielding after desiccation 17.3 per cent. of lipoids; among them he used only the alcohol-soluble group.

50 *Gerlier's Disease. (Kubisagari.) P. L. Couchoud.
51 Gallop Rhythm during and after Typhoid Fever. J. Mollard and A. Dumas. Commenced in No. 3.

50. **Gerlier's Disease.**—This is a peculiar nervous affection characterized by paresis, vertigo and ptosis. It attacks farm laborers and is known only in two localities, where it is endemic—on the Franco-Swiss frontier and in a district in the northern part of Japan. It was first discovered by Gerlier in 1884 and in recent years has been studied in Japan. The inhabitants of both regions are mostly hard-working peasants and the attacks come on only in the summer and when the patients are fatigued. Couchoud states that they last from one to ten minutes and the paresis involves the muscles of the limbs, back, neck, tongue, lips, jaw and eyelids. The head falls forward and there is such marked ptosis that the patient cannot see. The feet or hands cannot be lifted. There is no contracture. When cold weather comes on the attacks stop. The disease is found also in cats and cattle, and in both regions where it is known, the peasants live in close contact with their domestic animals. A small coccus, irregularly grouped and Gram-negative, has been isolated from the cerebrospinal fluid of patients, and when inoculated into cats has produced the disease. Thirty-two case-histories are given.

52 Postappendicitic Cicatricial Pericolitis Cured by Early Operation. (Péricolite membraneuse.) P. Wanner.
53 *Surgical Experiences at the Balkan Wars. N. Guerdjikoff.
54 Enlargement of the Prostate Treated by Bottini's Method. C. Perrier.

53. **Experiences in the Balkan Wars.**—Guerdjikoff had charge of a hospital that cared for 2,289 wounded and 654 sick soldiers during the two campaigns, and here presents some of his impressions of modern warfare. Gunshot and shrapnel wounds are never aseptic, he remarks, but if the first aid measures are properly applied and the wounds treated humanely by surgeons and nurses, if the wounds are not infected by officious meddling, very few infections result. Some of the wounded were brought across the mountains in ox-carts, and many of the injuries, furrows burrowed by bullets or seton wounds, the bullet boring straight through limb, chest or lung, had healed spontaneously on the way. He found that several small incisions through the skin materially hastened the healing of gaseous phlegmons. They were common, and developed rapidly, the second or third day after the injury, and gangrene developed in the cellular tissue and especially around the vessels. By releasing the gas through multiple small incisions, there was no further pressure on the cellular tissue and vessels, and as the blood-supply of the region returned to normal the tendency to gangrene was averted.

He frequently found that the bullet had turned completely around in its passage through the tissues, the point turned backward. The most remarkable course was that of a Mannlicher bullet which hit the skull in the left temple, ran around the skull, passed through the muscles at the back of the neck, then through the lung and back muscles, stopping finally under the skin near the second sacral vertebra.

The guiding principles in military surgery, he reiterates, are to refrain from doing harm, and to release pus. Soldiers under 25 are not fully developed, and after 35 they cannot stand what they could before, but between these age limits the recuperating power is almost incredible, and mutilating operations are rarely needed. He operated only in 194 cases, including all in which he removed the bullet or sequesters under a local anesthetic or made large incisions to release pus. The mortality was scarcely 1 per cent. including all who died from a superposed infectious disease, cholera, smallpox or tetanus. He adds that 3 per cent. of the Bulgarian surgeons at the seat of war succumbed to disease; two were shot and about 1.5 per cent. were wounded. He estimates that about 110,000 of the fighting force were wounded and 60,000 of them died of their wounds or disease while 10,000 were left more or less incapacitated. Boiled water to which 3 or 5 per cent. of tincture of iodin had been added was used freely to flush wounds and pus pockets, and proved a blessed reliance. A salve of 20 parts of balsam of Peru in 80 parts petrolatum was also much depended on. The total absence of all septic complications he ascribes to these and to the systematic use of moist dressings, gauze dipped in a weak disinfectant solution.

64 Improved Technic for Determination of Occult Blood. (Die Blutprobe nach Boas.) L. de Jager.

56. **Liver Tuberculosis.**—Tietze remarks that tuberculous lesions are found in the liver in nearly every case of miliary tuberculosis, but primary tuberculosis of the liver is so rare that the very possibility is denied by some. In the two cases of liver tuberculosis described the patients were boys of about 5 with pulmonary lesions and one had a tuberculous affection in the heel and lymph-nodes in the neck. The liver became very much enlarged and also the spleen, but there was no fever and no tenderness. Ascites required tapping occasionally and the pulse was much accelerated. Omentopexy was done in each case and an excised scrap of the liver showed tubercle growth. There were no signs of tuberculous peritonitis in either. The operation did not seem to benefit but the liver affection is evidently of a torpid nature and the boys have kept in fairly good condition. A course of roentgenotherapy was also given and the children were kept systematically lying down out of doors, even in winter.

61. **Indications for Radiotherapy of Cancer.**—Koblanck discusses which cancers are amenable to radiotherapy and which offer no chance for success with it. In order for it to be promising it must be possible to apply the radio-active substances close to the cancer and so that the rays can act chiefly on the young cancer cells on the periphery of the growth. The production of soft rays must be prevented. There must be around the cancer, and especially beneath the ulceration, tissue that is capable of regeneration. The cancer must not be too extensive, and there must not be any metastasis in other organs nor any cachexia. Only when all these six requirements are complied with is there any prospect of successful treatment by radiotherapy of internal or superficial cancer. Under favorable conditions, he remarks in conclusion, he would give radiotherapy the preference over operative measures, especially for a cancer of the lip. He has applied radiotherapy in 77 cancer cases to date and has studied the effect in numbers of other cases in the hands of confrères. Of his total cases only 13 were in an operable condition and in 8 of these constitutional disease forbade surgical intervention. The best results were obtained with cancroids of the face, cancers of uterus, vagina and vulva, and cancers of the tonsil and parotid gland. The action of radio-active substances is far from being always brilliant, but under careful selection of cases the proportion of successes will materially increase.

Correspondenz-Blatt für Schweizer Aerzte, Basel

65 *Multiplicity of Tumors. (Ueber Multiplizität von Geschwülsten.) F. Egli.
66 *Cancer of the Bile Passages and Liver. (Krebs der grossen Gallengänge und die primaren bösartigen Geschwülste der Leber.) S. Saltykow.

April 18, No. 16, pp. 481-512

67 Traumatic Ear Disease and Workmen's Compensation. (Begutachtung traumatischer Ohraffektionen.) W. Lindt and R. Nager.

65. **Multiple Tumors.**—Egli states that one or more tumors were found in 966 of 4,765 cadavers at the Basel institute of pathologic anatomy in the last seven years. There were primary multiple tumors in 263; that is, in 27.2 per cent. The tumors were malignant and single in 534; benign and single in 169; one of each in 77; in all the others there were various combinations of multiple malignant plus benign growths or growths in various different organs. In Egli's material of those with four or more tumors 2 were men and 10 women; with two tumors, 31 men and 98 women.

66. **Cancer of the Bile Apparatus Outside of the Gall-Bladder.**—Saltykow quotes the records from some other clinics to show the comparative rarity of this form of malignant disease, and then gives the necropsy details of a number of cases from his own experience in Switzerland. His list includes 9 primary carcinomas of the bile ducts; 8 of the liver; one case of both carcinoma and sarcoma in the liver, and 2 of sarcoma in the liver. In the bile-duct cancer cases, 2 of the patients were 34 and 35 and 2 over 75. Death occurs early, as the ducts soon become obstructed. All but one of the 19 cadavers were males.

E. Abderhalden and L. Grigorescu.
76 Surgical Work by the General Practitioner. O. Nordmann. Commenced in No. 15.
77 Sparing and Training the Digestive Apparatus. (Schonung und Uebung als Grundlinien der Ernährungstherapie.) F. Heinsheimer.

68. **The Continuous Bath in Mental and Nervous Disease.**—Weygandt traces the history of hydrotherapy in mental disease from the early days when Boerhave in the seventeenth century advocated as a therapeutic measure in mental disease the fright from being suddenly thrown into cold water. The continuous tepid bath has not only a welcome tranquilizing action but it prevents or aids in the healing of skin affections. In the thousands of cases in which he has applied it he has never noted any by-effects, except extremely rarely a slight tendency to syncope. Of course patients with weak hearts may require heart tonics and special care. Any special liability to eczema from the long immersion is easily counteracted by greasing the hands and feet or the whole body. The continuous bath is particularly useful in warding off decubitus in elderly paretics which so often hastens the fatal outcome in progressive paralysis. He asserts that even in his own experience alone, the effect of the continuous bath has been so beneficial on the metabolism and agitation that several patients improved to such an extent that they could return to business, and in numerous other cases it has prolonged life for years. He has an arrangement in the tub that rings an alarm when the water in the tub reaches 38 C.; if the water reaches 40 C. (104 F.) the alarm rings simultaneously in the superintendent's office. One attendant cannot attend to more than four tubs if the patients require much care. He adds that the continuous bath is an important aid also for neurasthenics; the effect is more dependable than mere bed rest as he found by personal experience during a nervous breakdown from over-work. It is also an important aid in healing up decubitus with spinal cord disease, mal perforans in tabes and in spastic paralysis.

69. **Operations on the Stomach.**—Schnitzler denounces gastro-enterostomy as a routine measure in operative treatment of gastric ulcer, saying that it is neither logical nor dependable. In one year recently he encountered five cases of recurrence of a gastric ulcer sooner or later after gastro-enterostomy had been done. More than a hundred cases of peptic ulcer after a gastro-enterostomy have been published, and this is probably far below the actual number. He has had to operate in ten such cases himself. The rule should be, he insists, that if any operation is to be done on the stomach, it should be ample resection. He has found a connection between the ulcer and the pyloric vein in such a number of cases that he is convinced that duodenal ulcer occurs more frequently than is generally recognized. They form fully one-fifth of all ulcers in this region.

71. **Poisoning from Nitrous Gases.**—Tetzner says that thirteen of the thirty-two fatal poisonings from this cause occurred from sawdust being strewn on spilt nitric acid. Nitrous gases are generated when this is done. The main

symptoms are on the part of the throat and lungs at first, but as these subside in the course of a few weeks, extreme debility, emaciation and nervous symptoms follow and are liable to be permanent. Out of twenty firemen who were seriously poisoned by the fumes during the burning of a chemical works, eleven were permanently incapacitated and one died. After the first disturbances there seems to be little wrong, but by the next day serious symptoms on the part of the air passages develop. A case is reported in detail: A pipe conveying the acid burst as a workman was employed nearby. He fell unconscious but recovered after a time and went downstairs and reported the break in the tube in the distilling room of the trinitrotoluol works where he was employed. A month later he complained still of pain in the chest, cough, subjective sounds, and he was pale, cyanotic, and unable to sleep much. There was a marked constant fine tremor of the entire body, including the head, which has persisted to date. No means of effectual treatment are known; heart tonics may be needed, and diluted lime water or other alkaline waters have been recommended, as also inhalation of oxygen, ammonia, sodium bicarbonate spray, or venesection plus saline infusion. Some recommend further to have from three to five drops of chloroform in a glass of water taken every ten minutes, until the maximal dose of 1.5 gm. has been taken in the course of one or two hours.

72. Indirect Injury from Concussion with Shrapnel Explosions.—Miloslavich describes seventeen cases of injury from shrapnel explosions without direct contact, no signs of burns or external injury. Unconsciousness for a time, intense headache, tinnitus, vertigo, disturbance in maintaining the balance, nystagmus and deafness point to special injury of the internal ear. In many cases the symptoms continued to grow more severe as time passed, indicating organic lesions. The injury of the internal ear in such cases is liable to escape discovery on a cursory examination.

74. Friedmann's Treatment in Lupus.—Treupel states that Friedmann's treatment was given to five lupus patients at Jena and in three no change in the lupus foci has been detected during the seven or eight weeks to date. In another case a transient bleaching of the lupus foci was noticed about two weeks after the first injection, but this was fleeting and no other change has been detected in the lupus regions during the two months to date. A small infiltration, followed by an abscess from which staphylococci were cultivated, developed at the site of the second intramuscular injection. The fifth patient was a robust young man with several lupus foci. At first one of the multiple lupus patches seemed to be a little flatter around the edges and there seemed to be less scaling. This apparently favorable effect from the treatment was but transient, no further improvement becoming manifest although this patient has been under observation for several months to date. There was a pronounced temperature reaction to the *Simultaninjektion* and severe jaundice which much debilitated the patient so he has lost over 19 pounds in weight and the jaundice has not subsided entirely although nine weeks have elapsed. Treupel remarks in conclusion that as others have reported isolated cases of jaundice after Friedmann treatment, and even fatalities have been published, and also instances of contamination of the remedy with staphylococci and other bacteria, and as no improvement of any practical significance was observed in his experience, he has no intention of using the remedy further in its present form.

78. Effect of Medicated Douches on the Bacterial Content of the Vagina.—Zweifel tried douches of various salts of mercury, potassium permanganate, etc., and found that the number of bacteria were reduced temporarily but that they returned after a short time. He also tried Schweitzer's method of irrigating the vagina in cases with a pathologic secretion with a 0.5 per cent. solution of lactic acid, with a view to preventing puerperal fever. His conclusion is that douches of this kind kept up for a period of ten days or longer really have a beneficial effect.

80. Treatment of Uterine Cancer with Mesothorium.—Weinbrenner describes three cases operated on after mesothorium treatment for carcinoma of the uterus. The operation wounds healed very slowly, and this he attributes to the effect of the mesothorium. Moreover, there seemed to be a tendency to the formation of fistulas long afterward from necrosis of the degenerated connective tissue.

84. Creatinin Test for Examination of Kidney Functioning.—Neubauer calls attention to the instructive difference in the elimination of creatinin by sound and diseased kidneys after ingestion of 1.5 gm. dissolved in 100 or 150 c.c. of sweetened water. He has thus tested the functional capacity of the kidneys in ten healthy persons and seventy patients. The healthy eliminate in the urine in the next six hours from 60 to 90 per cent. of the creatinin thus ingested and all or nearly all of the rest in the following six hours. With diseased kidneys less than 20 per cent. is eliminated in the first six hours and the elimination drags over days. This functional weakness in regard to creatinin is apparent in every case in which any of the other functions of the kidneys are impaired and hence this test is particularly sensitive for any form of derangement. The findings were most pronounced when there were signs of uremia, regardless of whether there was hydrops or not. The creatinin test is of little diagnostic import when only one kidney is diseased. With known disease of one kidney, defective elimination of the creatinin is a sign that the supposed sound mate is impaired also. Instructive findings can be obtained by catheterization of the ureters and comparison of the natural creatinin content. The natural creatinin content of the blood is also augmented in case of impaired permeability of the kidneys. The proportion of creatinin in the body fluids is best determined with a color scale.

85. Resection of Ribs or a Filling in Treatment of Pulmonary Tuberculosis.—Wilms' latest communication on his method of immobilizing the lung was mentioned in these columns May 9, p. 1513. He here extols the superior advantages of a filling for the purpose, plugging the space with

56. **Liver Tuberculosis.**—Tietze remarks that tuberculous lesions are found in the liver in nearly every case of miliary tuberculosis, but primary tuberculosis of the liver is so rare that the very possibility is denied by some. In the two cases of liver tuberculosis described the patients were boys of about 5 with pulmonary lesions and one had a tuberculous affection in the heel and lymph-nodes in the neck. The liver became very much enlarged and also the spleen, but there was no fever and no tenderness. Ascites required tapping occasionally and the pulse was much accelerated. Omentopexy was done in each case and an excised scrap of the liver showed tubercle growth. There were no signs of tuberculous peritonitis in either. The operation did not seem to benefit but the liver affection is evidently of a torpid nature and the boys have kept in fairly good condition. A course of roentgenotherapy was also given and the children were kept systematically lying down out of doors, even in winter.

61. **Indications for Radiotherapy of Cancer.**—Koblanck discusses which cancers are amenable to radiotherapy and which offer no chance for success with it. In order for it to be promising it must be possible to apply the radio-active substances close to the cancer and so that the rays can act chiefly on the young cancer cells on the periphery of the growth. The production of soft rays must be prevented. There must be around the cancer, and especially beneath the ulceration, tissue that is capable of regeneration. The cancer must not be too extensive, and there must not be any metastasis in other organs nor any cachexia. Only when all these six requirements are complied with is there any prospect of successful treatment by radiotherapy of internal or superficial cancer. Under favorable conditions, he remarks in conclusion, he would give radiotherapy the preference over operative measures, especially for a cancer of the lip. He has applied radiotherapy in 77 cancer cases to date and has studied the effect in numbers of other cases in the hands of confrères. Of his total cases only 13 were in an operable condition and in 8 of these constitutional disease forbade surgical intervention. The best results were obtained with cancroids of the face, cancers of uterus, vagina and vulva, and cancers of the tonsil and parotid gland. The action of radio-active substances is far from being always brilliant, but under careful selection of cases the proportion of successes will materially increase.

67 Traumatic Ear Disease and Workmen's Compensation. (Begutachtung traumatischer Ohraffektionen.) W. Lindt and R. Nager.

65. **Multiple Tumors.**—Egli states that one or more tumors were found in 966 of 4,765 cadavers at the Basel institute of pathologic anatomy in the last seven years. There were primary multiple tumors in 263; that is, in 27.2 per cent. The tumors were malignant and single in 534; benign and single in 169; one of each in 77; in all the others there were various combinations of multiple malignant plus benign growths or growths in various different organs. In Egli's material of those with four or more tumors 2 were men and 10 women; with two tumors, 31 men and 98 women.

66. **Cancer of the Bile Apparatus Outside of the Gall-Bladder.**—Saltykow quotes the records from some other clinics to show the comparative rarity of this form of malignant disease, and then gives the necropsy details of a number of cases from his own experience in Switzerland. His list includes 9 primary carcinomas of the bile ducts; 8 of the liver; one case of both carcinoma and sarcoma in the liver, and 2 of sarcoma in the liver. In the bile-duct cancer cases, 2 of the patients were 34 and 35 and 2 over 75. Death occurs early, as the ducts soon become obstructed. All but one of the 19 cadavers were males.

76 Surgical Work by the General Practitioner. O. Nordmann. Commenced in No. 15.

77 Sparing and Training the Digestive Apparatus. (Schonung und Uebung als Grundlinien der Ernährungstherapie.) F. Heinsheimer.

68. **The Continuous Bath in Mental and Nervous Disease.**—Weygandt traces the history of hydrotherapy in mental disease from the early days when Boerhave in the seventeenth century advocated as a therapeutic measure in mental disease the fright from being suddenly thrown into cold water. The continuous tepid bath has not only a welcome tranquilizing action but it prevents or aids in the healing of skin affections. In the thousands of cases in which he has applied it he has never noted any by-effects, except extremely rarely a slight tendency to syncope. Of course patients with weak hearts may require heart tonics and special care. Any special liability to eczema from the long immersion is easily counteracted by greasing the hands and feet or the whole body. The continuous bath is particularly useful in warding off decubitus in elderly paretics which so often hastens the fatal outcome in progressive paralysis. He asserts that even in his own experience alone, the effect of the continuous bath has been so beneficial on the metabolism and agitation that several patients improved to such an extent that they could return to business, and in numerous other cases it has prolonged life for years. He has an arrangement in the tub that rings an alarm when the water in the tub reaches 38 C.; if the water reaches 40 C. (104 F.) the alarm rings simultaneously in the superintendent's office. One attendant cannot attend to more than four tubs if the patients require much care. He adds that the continuous bath is an important aid also for neurasthenics; the effect is more dependable than mere bed rest as he found by personal experience during a nervous breakdown from over-work. It is also an important aid in healing up decubitus with spinal cord disease, mal perforans in tabes and in spastic paralysis.

69. **Operations on the Stomach.**—Schnitzler denounces gastro-enterostomy as a routine measure in operative treatment of gastric ulcer, saying that it is neither logical nor dependable. In one year recently he encountered five cases of recurrence of a gastric ulcer sooner or later after gastro-enterostomy had been done. More than a hundred cases of peptic ulcer after a gastro-enterostomy have been published, and this is probably far below the actual number. He has had to operate in ten such cases himself. The rule should be, he insists, that if any operation is to be done on the stomach, it should be ample resection. He has found a connection between the ulcer and the pyloric vein in such a number of cases that he is convinced that duodenal ulcer occurs more frequently than is generally recognized. They form fully one-fifth of all ulcers in this region.

71. **Poisoning from Nitrous Gases.**—Tetzner says that thirteen of the thirty-two fatal poisonings from this cause occurred from sawdust being strewn on spilt nitric acid. Nitrous gases are generated when this is done. The main

symptoms are on the part of the throat and lungs at first, but as these subside in the course of a few weeks, extreme debility, emaciation and nervous symptoms follow and are liable to be permanent. Out of twenty firemen who were seriously poisoned by the fumes during the burning of a chemical works, eleven were permanently incapacitated and one died. After the first disturbances there seems to be little wrong, but by the next day serious symptoms on the part of the air passages develop. A case is reported in detail: A pipe conveying the acid burst as a workman was employed nearby. He fell unconscious but recovered after a time and went downstairs and reported the break in the tube in the distilling room of the trinitrotoluol works where he was employed. A month later he complained still of pain in the chest, cough, subjective sounds, and he was pale, cyanotic, and unable to sleep much. There was a marked constant fine tremor of the entire body, including the head, which has persisted to date. No means of effectual treatment are known; heart tonics may be needed, and diluted lime water or other alkaline waters have been recommended, as also inhalation of oxygen, ammonia, sodium bicarbonate spray, or venesection plus saline infusion. Some recommend further to have from three to five drops of chloroform in a glass of water taken every ten minutes, until the maximal dose of 1.5 gm. has been taken in the course of one or two hours.

72. **Indirect Injury from Concussion with Shrapnel Explosions.**—Miloslavich describes seventeen cases of injury from shrapnel explosions without direct contact, no signs of burns or external injury. Unconsciousness for a time, intense headache, tinnitus, vertigo, disturbance in maintaining the balance, nystagmus and deafness point to special injury of the internal ear. In many cases the symptoms continued to grow more severe as time passed, indicating organic lesions. The injury of the internal ear in such cases is liable to escape discovery on a cursory examination.

74. **Friedmann's Treatment in Lupus.**—Treupel states that Friedmann's treatment was given to five lupus patients at Jena and in three no change in the lupus foci has been detected during the seven or eight weeks to date. In another case a transient bleaching of the lupus foci was noticed about two weeks after the first injection, but this was fleeting and no other change has been detected in the lupus regions during the two months to date. A small infiltration, followed by an abscess from which staphylococci were cultivated, developed at the site of the second intramuscular injection. The fifth patient was a robust young man with several lupus foci. At first one of the multiple lupus patches seemed to be a little flatter around the edges and there seemed to be less scaling. This apparently favorable effect from the treatment was but transient, no further improvement becoming manifest although this patient has been under observation for several months to date. There was a pronounced temperature reaction to the *Simultaninjektion* and severe jaundice which much debilitated the patient so he has lost over 19 pounds in weight and the jaundice has not subsided entirely although nine weeks have elapsed. Treupel remarks in conclusion that as others have reported isolated cases of jaundice after Friedmann treatment, and even fatalities have been published, and also instances of contamination of the remedy with staphylococci and other bacteria, and as no improvement of any practical significance was observed in his experience, he has no intention of using the remedy further in its present form.

84. **Creatinin Test for Examination of Kidney Functioning.**—Neubauer calls attention to the instructive difference in the elimination of creatinin by sound and diseased kidneys after ingestion of 1.5 gm. dissolved in 100 or 150 c.c. of sweetened water. He has thus tested the functional capacity of the kidneys in ten healthy persons and seventy patients. The healthy eliminate in the urine in the next six hours from 60 to 90 per cent. of the creatinin thus ingested and all or nearly all of the rest in the following six hours. With diseased kidneys less than 20 per cent. is eliminated in the first six hours and the elimination drags over days. This functional weakness in regard to creatinin is apparent in every case in which any of the other functions of the kidneys are impaired and hence this test is particularly sensitive for any form of derangement. The findings were most pronounced when there were signs of uremia, regardless of whether there was hydrops or not. The creatinin test is of little diagnostic import when only one kidney is diseased. With known disease of one kidney, defective elimination of the creatinin is a sign that the supposed sound mate is impaired also. Instructive findings can be obtained by catheterization of the ureters and comparison of the natural creatinin content. The natural creatinin content of the blood is also augmented in case of impaired permeability of the kidneys. The proportion of creatinin in the body fluids is best determined with a color scale.

85. ***Resection of Ribs or a Filling* in Treatment of Pulmonary Tuberculosis.**—Wilms' latest communication on his method of immobilizing the lung was mentioned in these columns May 9, p. 1513. He here extols the superior advantages of a filling for the purpose, plugging the space with

adipose tissue or paraffin if the same results can be realized with it. Whether this can be done depends, he says, on the size of the space to be filled. For various reasons the lower lobe cannot be immobilized so well by a filling, but it answers finely for the upper lobe, and by combining a filling to compress the upper lobe with resection of ribs, close to spine and sternum, to immobilize the lower lobe, the entire lung on one side can thus be shut off from functioning. This combination makes less demands on the patient, and the effect in his cases to date has been extremely good. He used a paraffin filling in two cases and found it satisfactory to date. In others he implanted adipose tissue to plug the space; it was taken from the patient himself in two cases, in three from other patients. Everything seems to indicate that the fat heals smoothly in place and maintains a durable compression. With this filling technic he insists that we are justified in applying immobilization treatment to recently developed and comparatively small cavities.

91. **Symptom of Cerebellar Abscess.**—Mann noticed that a child with cerebellar abscess causing deep somnolency, warded off persons attempting to rouse him by making defensive movements with the arm of the sound side alone. He did not use at all the arm on the side of the abscess, although it was not paralyzed or injured. The same tendency to refrain from using the arm on the diseased side was evident also in another patient convalescing from an operation for a cerebellar abscess. Mann found that a similar experimental experience was published by Luciani twenty years ago; he related that after removal of part of the cerebellum of a dog, if one ear was pinched with forceps the dog soon scraped off the forceps if it was the ear on the sound side, but he made no attempt to scrape it off if it was on the ear on the same side as the cerebellar lesion. Mann found that the patient used both hands to defend himself in a recent case of abscess in a frontal lobe. The means he took to elicit the defensive movements in these cases was holding the patient's nose.

99 Varices in Thoracic Duct. A. Priesel.
100 Psychology of Children. (Zur Kinderpsychologie und Neurosenforschung.) A. Adler.

95. **Experimental and Clinical Study of Chronic Tobacco Poisoning.**—Favarger has for years made a study of this subject and here gives the details of twenty-one cases of disturbances on the part of the heart from abuse of tobacco. Experiments on animals seemed to indicate that the nicotin element alone is responsible for them. The first sign of trouble is palpitations, and if the abuse of tobacco is not excessive this may be the only symptom. With continued abuse, arhythmia and intermittent or abnormally slow or fast pulse may follow with sensations of oppression, precordial distress, weakness and insufficiency of the myocardium, dyspnea, cardial asthma, Cheyne-Stokes, cyanosis and finally fatal paralysis of the heart. Types of all these are included in the cases he reports, six with fatal paralysis of the heart. It is his impression that abuse of cigar smoking has a more deadening influence, the senses and memory becoming less acute and the heart suffering more than from excessive cigarette smoking. With the latter the symptoms of abnormal excitability of the nervous system predominate. The dependence of certain gastro-intestinal disturbances on nicotin poisoning has been confirmed innumerable times, he says, by their coming and going parallel to abuse and abstention from smoking. They range from the common lack of appetite, diarrhea or constipation to extreme emaciation and gastric ulcer; the latter may be the direct result of defective blood-supply from vascular spasm or weak heart action, these factors possibly supplemented by swallowing the smoke and particles of tobacco. He knows of many cases of myocardium trouble from tobacco poisoning in which there are no signs of arteriosclerosis. The latter is common in nicotin poisoning but not so universal as some assume. The myocardium symptoms are those that correspond to fatty degeneration, but post-mortem examination is rarely permitted in cases of nicotin poisoning as they are generally encountered in private practice.

96. **Differential Diagnosis of Intrathoracic Goiter.**—Engel and Holitsch call attention to the abnormal width of the shadow cast by the organs above the heart and apparently below the thyroid when the enlarged thyroid extends downward behind the sternum. This abnormally wide middle shadow may extend beyond the inner third of the clavicle possibly to its middle. The trachea may also deviate from the middle line even in the neck, while the arch of the aorta is pushed also to one side or downward. As the patient swallows, the entire shadow of the middle portion rises from 0.5 to 1 cm. and then falls again; with an aneurysm there is not this displacement during swallowing. The edges of an aneurysm shadow show pulsation toward every direction but there is no pulsation evident in the shadow of a substernal goiter, or it is only propagated in one direction. The shadow of the goiter is always sharply defined from the lung while the shadow of a tumor generally extends more or less into the lung. The most instructive sign, however, is the rising up of the shadow or the area of dulness over the manubrium as the patient swallows. If the substernal goiter is fastened down by adhesions, even this sign may fail.

104 *Exfoliating Dermatitis. B. Sperk.
105 Early Editions of Glisson's "De Rachitide." E. Ebstein.

104. **Exfoliative Dermatitis.**—Sperk describes fifteen cases of exfoliative dermatitis. It is a disease of the first few weeks of life. In several cases he examined the bladder contents bacteriologically, and in all these cases he demonstrated staphylococci both microscopically and by culture. In one case he found *Staphylococcus pyogenes albus* in the blood. The affection seems to belong, therefore, in the group of staphylococcic pyodermias and this explains why it is so easily transmitted and why isolation is so necessary in children's hospitals.

112. **Pruritus.**—Thibierge remarks that with generalized pruritus internal measures to combat the intestinal fermentations, liver, uterus or kidney derangement or other trouble causing the diffuse toxic pruritus may be aided with pastes containing menthol or phenol. With localized pruritus, especially at the anus or vulva, more energetic local measures are needed, and he commends silver nitrate in particular, in quite concentrated solutions for anal pruritus, or even applying the nitrate pencil. This hurts for a few hours, but gives the greatest relief. He has found lumbar puncture, repeated two or three times, successful in general or local pruritus in

some cases absolutely rebellious to all other measures. It is not necessary to withdraw more than 3 or 4, or at most 6 c.c. of the cerebrospinal fluid.

118 *Magnesium Sulphate in Treatment of Chorea. (La corea di Sydenham trattata col metodo Marinesco.) A. Natali.
119 *Treatment of Traumatic Extravasation of Blood in the Knee. (Il metodo cinetico del de Thooris nelle emartrosi traumatiche del ginocchio.) U. Pasini.

118. **Magnesium Sulphate in Chorea.**—Natali has applied intraspinous injections of magnesium sulphate in seven cases of chorea minor and one of chronic chorea. The affection was of fourteen, twenty-five or sixty days' duration or from one to seven years. With the exception of one case in which the attacks were almost continuous, there were periods of remission. He injected from 1.5 to 3 c.c. of a 7 to 25 per cent. solution. Three of the patients were entirely and four nearly cured, but the chronic chorea did not seem to be modified. The improvement was gradual and progressive. A course of arsenic seemed to hasten the cure. This treatment naturally should be reserved for the more serious and rebellious cases.

119. **Treatment of Traumatic Hemarthrosis in the Knee.**—Pasini extols de Thooris' method of treatment which requires no operation, no appliances and no drugs, nothing but the skillful application of movements. The patient is kept on his back in bed, not allowing him to get up on any pretext or flex his knee, and the bed-clothes should leave the leg free. He should then raise his leg without bending it at the knee. This extension of the leg on the thigh has a direct curative action on traumatic extravasations in the knee. The leg should be lifted up until it is at a right angle to the horizontal body. At first the movement has to be done passively, and then be aided for a time until he can do it alone. The limb should be raised slowly and regularly and lowered in the same way, repeating the movement often but not to the point of fatigue, and distributing the movements at regular intervals over the day. During the intervals a wet pack is applied but without the least compression. It is useful also to contract the extensor muscles from time to time, even in repose. The sign that conditions have improved so that the patient can get up is when the patella slides out from the grasp of the finger and thumb holding it lengthwise, the leg hanging loose, when the patient contracts suddenly his extensor muscles. This occurs in normal conditions but the patella does not slide out from the grasp in this way when there has been extravasation of blood in the joint for some months. When first allowed to get up, the patient should complete the treatment by holding the joint stiff.

134 *Function of the Thymus. I. S. Shimizu.
135 The Pepsin in the Urine. (Harnpepsin.) S. Okada.

130. **Rat-Bite Disease.**—Ogata's clinical and experimental research has confirmed the fact, he says, that a fungus with which the individual is inoculated when bitten by the rat is the cause of the clinical picture known as rat-bite disease. The fungus seems to be of the aspergillus family and to be readily destroyed by mercurial inunctions, improvement and complete cure following on a course of mercurial inunctions. The three cases here reported bring to eleven the cases he has encountered.

134. **Thymus Functioning.**—Shimizu found that the serum from rabbits treated beforehand with dog thymus caused marked destruction of thymus tissue when injected into young dogs, in addition to phenomena of anaphylaxis. There seems to be no doubt that the prepared serum contains an actual thymolysin. It acts on the dogs in a way similar to the disturbances in development which follow removal of the thymus in young dogs. The medullary portion of the thymus seems to have a different function from the cortex, and it is probably the medullary portion, he says, which secretes the internal secretion.

136 *An Endemic Adenomycosis in Brazil. (Nova molestia humana.) E. Dias.
137 *Morbidity of Rio. (Nosologia e mortalidade da cidade do Rio de Janeiro.) P. Barbosa and S. Vianna. Commenced in No. 11.

136. **Endemic Adenomycosis.**—Dias describes an affection of the lymph-nodes in the neck which is endemic in his district, Minas, and which can be reproduced in animals. Separate lymph-nodes swell enormously but never suppurate; the symptoms suggest leukemia or tuberculosis at first. The course is always fatal; sometimes in six or eight months, or not for two or three years. Potassium iodid seems to have benefited in one case at least. He has four under observation at present. A mycelium can be cultivated from fluid aspirated from one of the lymph-nodes affected, and inoculation of white rats kills them in a few days.

137. **Morbidity of Rio.**—In this review of sanitary conditions in Rio we note that the mortality from plague has

dropped gradually since 1903 from 48 per hundred thousand inhabitants to 0.81; leprosy keeps about the same, 2.09 in 1890 and 3.33 in 1912; beriberi has dropped from 16 in 1903 to 1.43 in 1912; diphtheria has ranged from 9.1 in 1868 to 43.4 in 1883. Then came a sudden drop to 6.5 in 1890; since then it has ranged from 1.3 to 6.4—the latter figure in 1912. There have been only 24 deaths in all from scarlet fever since 1903. The deaths from dysentery are what swell the mortality at Rio, the figures in 1869 being 41.68 and in 1912, 18.81. The general mortality has been 20.5 per thousand, surpassed by cities in Egypt, India and Russia, Naples and Trieste.

154 *Artificial Respiration in Case of Central Paralysis of the Respiration. (Künstliche Atmung bei zentraler Atemlähmung.) P. Bode.
155 *Application of Large Magnet in Gastro-Intestinal Derangement. G. Plotkin.
156 Concentrated Solutions of Salvarsan and Neosalvarsan. J. Grunberg.

154. **Artificial Respiration for Central Respiratory Paralysis.**—Bode's first patient was a man of 38 with a focus of softening in the third and fourth ventricles with resulting compression of the respiration center. The skull had been trephined on the assumption of an abscess in the brain, but the focus was not reached. An hour later respiration stopped completely but the heart was kept beating by artificial respiration for fifteen hours, when death finally ensued. The second patient was a woman of 29 with some organic brain process which caused sudden arrest of the respiration; she too was kept alive for fifteen hours by artificial respiration. There was no necropsy. The original Silvester method proved the simplest and most effectual in these cases, but when the artificial respiration has to be applied in the course of an operation, Bode prefers the Schuller technic on account of asepsis.

155. **The Magnet in Gastro-Intestinal Diseases, Etc.**—The Journal mentioned recently Payr's work with a large magnet applied to the abdomen after the patient has taken a suspension of fine iron particles. The magnet acting on the iron draws the loops of intestines around and lifts them up, and it is possible in this way to exercise them at will. Plotkin here extols the capabilities of the method, saying that it can be applied to dilate a stricture or diverticulum, to aid in correcting displacement of the uterus and in prophylaxis and cure of adhesions. He sees such a wide range of usefulness for the measure that he says he thinks that digestive diseases, at least, are entering on an era of "ferromagnetism." (See abstract 134, p. 171).

Hygiea, Stockholm

April 1, LXXVI, No. 7, pp. 385-448

159 *Hemolytic Jaundice. (Hämolytisk ikterus.) O. Lindbom.

159. **Hemolytic Jaundice.**—After a comprehensive review of what has been published on this subject to date, Lindbom reports a case from his own practice. His patient was a young woman and the attacks of pain and intense jaundice were long attributed to gall-stones. Investigation revealed five other cases in the same family; three of the woman's sisters, her mother and her grandmother all had more or less jaundice and it dated from early childhood. There was also more or less anemia, with characteristic blood-findings; discovery of these other cases in the family threw discredit on the diagnosis of gall-stones, especially as the spasmodic pain was referred to the left side and no point of special tenderness could be found in the gall-bladder region. Even if an operation had revealed gall-stones, their removal would not have affected the main element in the syndrome, the excessive destruction of red corpuscles. A course of cholesterin treatment was instituted, a daily dose of 1.5 gm. cholesterin dissolved in oil. If this fails the spleen will be exposed to the Roentgen rays and, as a last resort, splenectomy will be proposed. Hemolytic jaundice may prove more common than now supposed. It is highly probable that many cases of it have been mistaken for gall-stone trouble; the decisive symptom is the reduced resisting power of the red corpuscles to hypotonic salt solution.

Ugeskrift for Læger, Copenhagen

April 23, LXXVI, No. 17, pp. 727-778

160 *Treatment of Puerperal Mastitis. (Om behandling af galactoforitis.) E. Hauch.

160. **Treatment of Puerperal Mastitis.**—Hauch describes the methods of treating inflammation of the milk ducts at the Copenhagen maternity. The child is allowed to nurse as long as it will, and then afterward the breast is massaged and milked entirely dry and heat is applied, or with a powerful breast-pump it is emptied dry and then an ice-bag is applied. None of the fifty-five cases treated with massage and heat came to an abscess; as a rule the temperature speedily dropped, although in ten cases there was a relapse later. There was a relapse in only eight of the seventy cases treated with vacuum suction and ice, so that the latter technic is now regarded as the best, especially as recovery proceeds more rapidly. An abscess developed in one of the ice-treated cases. None of the children seemed to suffer from the effects of the galactophoritis; in about a third of the first group of cases supplementary artificial feeding became necessary, and in about a fifth of the ice-treated cases (16 to 55 and 15 to 70). Massage is liable to do harm; it may rupture a distended milk duct in unskillful hands, while the vacuum-suction treatment can scarcely do harm under any circumstances, and it does not cause pain like the massage.

HAS THE AMERICAN GYNECOLOGICAL SOCIETY DONE ITS PART IN THE ADVANCEMENT OF OBSTETRICAL KNOWLEDGE? *

J. WHITRIDGE WILLIAMS
BALTIMORE

When casting about for a suitable subject on which to address you, it occurred to me to read all of the obstetric articles which have been contributed to the society since its inception, in the hope that their analysis might prove interesting to our older members and stimulating to the younger ones.

During the thirty-eight years of its existence, 1,010 papers have been contributed, 664 on gynecologic and 346 on obstetric topics, including extra-uterine pregnancy. Consequently, a little more than one-third (34.2 per cent.) fall in the latter category and were contributed by 128 persons. Of these, 53 made only a single contribution, 50 read from two to four papers each, 22 from five to nine, and 3 ten or more papers, so that somewhat less than one-fifth of the entire number were frequent contributors.

I found the task of reading the articles very interesting and fairly profitable, as they set forth in a more or less consecutive manner the history of obstetrics for the past forty years, and served to impress me anew with the great progress which had been made in the technical side of our art.

During this period we have witnessed many changes, the most far-reaching being the development of aseptic technic and the establishment of the bacterial origin of puerperal infection, as the result of which the lying-in hospital has been converted from the most dangerous to the safest place for the delivery of women. Every stage in the development of this doctrine can be traced in our *Transactions*. In the early volumes one finds articles showing that vaginal and intra-uterine douches could be administered with safety, along with other articles giving directions for the most rudimentary antiseptic technic.

It may surprise some of our younger members to learn that, so late as 1884, Albert H. Smith, in his presidential address, vigorously combated the bacterial origin of infection; and, on the other hand, that some members of the society took an active part in the transformation of the lying-in hospitals. For example, we read with pride of Garrigues' achievements in 1883 at the New York Maternity Hospital. In the first nine months of that year, thirty deaths from infection had occurred in 345 deliveries, but the changes which he so intelligently introduced effected such a revolution that during the last three months of the year not a single patient died, and only three of the ninety-five presented a rise in temperature. Furthermore, Polk told us that when he graduated in medicine, delivery in a lying-in hospital was far more dangerous than an engagement in the bloodiest battle, for, during his internship at Bellevue he saw forty-five women die out of the sixty who had been delivered during a single month.

In the papers of Garrigues and Jewett we can also trace the history and development of laparo-elytrotomy, the latter informing us that six women and seven children had been saved in eleven operations up to 1885. This operation is of great interest to students of medical history, as its invention by Thomas represents one of the very few American contributions to obstetrics; and its recent resuscitation under the guise of extraperitoneal cesarean section shows that his conceptions were well founded.

The conversion of cesarean section from "the most dangerous operation in surgery," to one in which the results are so good that it is in imminent danger of being abused by "knife-loving" obstetricians and by surgeons who know nothing of the resources of obstetrics, can be graphically followed. The early accounts of tardy operations for the removal of a dead child from an exhausted and infected woman stand in marked contrast to the first elective operation performed by Lusk in 1887, and particularly to the long series of successful operations which were afterwards reported by many of our fellows.

Following Harris' paper in 1892, entitled "The Remarkable Results of Antiseptic Symphyseotomy," we can trace the development and fall from favor of that operation, as well as the scant recognition accorded the usefulness of its sister operation, pubiotomy.

One of the most interesting phases of obstetric history is afforded by the fifty-one papers on extra-uterine pregnancy. In these we can trace the evolution of a pathologic curiosity into a condition of every-day occurrence. Furthermore, we can follow the education of the profession in its diagnosis, as well as the gradual development of means for its cure, first by electricity or by the injection of morphin into the sac, and later by surgical methods. We can likewise trace the development of the *furor operativus* to the point at which the diagnosis of the condition came to mean immediate operation without regard to the condition of the patient, until Robb's experimental work demonstrated the fact that interference might frequently be deferred with benefit to the patient.

---

* Presidential address, delivered before the American Gynecological Society, 1914.

Many other changes can be followed with interest and profit; for example, the slow recognition of the fact that occiput-posterior presentations should not be regarded as abnormal, but that, if left alone, they will usually terminate spontaneously with but little greater difficulty than when the occiput is directed anteriorly.

We can also follow the evolution of more correct views concerning the employment of forceps and the recognition of the fact that its improper use is a potent factor in the death of the child and in the production of serious lesions on the part of the mother. Likewise, we can read the discussions concerning the value of axis-traction; but, just as its merits were beginning to be recognized, its field of usefulness became markedly restricted by the knowledge that it is not the ideal means of overcoming mechanical obstruction.

It is interesting to recall the fact that, in the early days of the society, not even trained obstetricians were agreed as to the necessity for the immediate repair of birth injuries; for, at the first meeting in 1876, Goodell contributed an important communication setting forth the innocuousness and desirability of routine perineal repair.

I might continue to recount many other advances in the practical treatment of childbirth and its complications, but time will not permit. Consequently, I shall refer only to the abuse of ergot. Its employment was considered on several occasions in the early days of the society, when the consensus of opinion developed that it was indicated only after the extrusion of the placenta. It may also interest you to be reminded that it was frequently administered so freely in the treatment of abortion as to give rise to chronic ergot poisoning, and that John Goodman reported an instance in which it had led to gangrene of the extremities. I lay stress on this almost forgotten fragment of medical history, for I believe that unless correct teachings concerning the action of and the indications for the use of the various preparations of pituitary gland substance soon become current, a similar crusade will be necessary to check the abuse of this powerful therapeutic agent.

After listening to this imperfect enumeration of the advances of obstetrics as portrayed in our *Transactions,* one's first impulse is a feeling of pride in the achievements of his colleagues and a sense of satisfaction with the part we have played in developing this branch of medicine. Closer and candid consideration, however, compels the depressing confession that such feelings are not justified, but that, on the contrary, we have done virtually nothing in developing even the practical side of our art. We have been content merely to follow in the footsteps of others, occasionally quite sluggishly, and to reap what we have not sown.

Careful analysis of our *Transactions* has failed to convince me that scarcely a single, fundamental contribution to practical obstetrics has been made to this society, and I feel that you will agree with me when you hear the facts.

We did nothing fundamental in connection with the question of puerperal infection; Holmes, Semmelweis, Pasteur and Tarnier laid its theoretic foundations, while the practical utility of antiseptic precautions had been demonstrated in Germany and France before we seriously faced the matter.

The modern cesarean section originated in Germany, and five years elapsed after the publication of Sänger's monograph before we were able to report a single, successful operation.

The same may be said of symphyseotomy and pubiotomy; and it was not until after Harris had called attention to the results obtained in Italy and France that we showed signs of being aware that the operation had been successfully resuscitated. Even in connection with extra-uterine gestation we have little reason to be proud, as the operation after rupture came to us from Tait, and Veit had given directions for diagnosticating unruptured tubal pregnancy four years before the subject was mentioned before this society.

Likewise, our views concerning the mechanism of labor in occiput-posterior presentations were woefully behind the times; and it required years for us to reach the position which Naegele had attained in 1838. Naturally, it might have been supposed that the mechanical ingenuity of this nation would have led to improvements in the forceps; but not so. While we were inventing narrow-bladed instruments which might be applied through a cervix the size of a five-cent piece, Tarnier had worked out the principle of axis-traction, which we accepted only after considerable hesitation.

I shall not continue this doleful list, as it seems sufficient to prove that we have added practically nothing to the technical side of obstetrics, while the analysis which I am about to present will show that we have done even less on the scientific side.

For purposes of analysis, I have classified the 346 obstetric papers into thirty-two groups, as shown by the accompanying table.

ANALYSIS OF THE OBSTETRIC PAPERS, 1876-1913

* The first of these columns indicates total number; the second, the number of creditable papers, and the third, the number of excellent papers.

With as little bias as possible, I have attempted to form a judgment as to the value of the papers, and have designated as good or creditable those in which the subject under consideration was presented in a useful and attractive manner, but without adding anything new, and as excellent such papers as have contributed, even to a slight extent, to the sum total of obstetric knowledge. Judged by these criteria, I have placed forty-two papers in the former and twenty-seven in the latter category — 12 and 8 per cent., respectively. Consequently, it would appear that on the average less than two creditable papers have been contributed each year and that only two contributions could be expected in three years. Surely this is not a showing of which our society can be proud.

On the other hand, I would call attention to the fact that seventy papers, or somewhat less than one-fifth of the entire number, were purely casuistic in character, and were based on the history of one or at most two cases. Though often interesting, papers of this character are usually of little value and are better suited for presentation before a local medical society than before a national association supposedly composed of scientific men.

Most of the remaining 207 papers were unobjectionable, yet, while sometimes provocative of interesting discussion, they served merely as vehicles for the expression of the personal experiences of their writers. A small number, including an occasional thesis for admission, were valueless and sometimes puerile. In general, these papers were practical in character and dwelt but little on the scientific or theoretic aspects of the subject. Many of them were based on an experience too small to justify authoritative conclusions and were such as might be expected from young assistants after a few years' service in a well-conducted clinic. It would appear that their chief function was to afford the authors an opportunity to air their views at the expense of the society on topics of more or less general interest and to educate the general practitioner, rather than to stimulate the free exchange of thought between competent experts with a view to broadening their field of vision and increasing the general store of knowledge.

Reverting to the analysis of the papers, I found six creditable and four excellent communications among the forty-six included in the four groups devoted to pregnancy (*A*). I was greatly surprised, however, at the dearth of papers on many important subjects. For example, there was an entire absence of reference to the biologic and biochemical aspects of pregnancy, and, with the exception of a demonstration by Minot, no mention was made of the fundamental problems connected with placentation. Nothing was said of normal metabolism during pregnancy, and, had we been dependent on the society for information, we should have been unaware of the significance of Abderhalden's pregnancy reaction.

Furthermore, only once during the life of the society has reference been made to the importance of syphilis in connection with the child-bearing process, and that only in an incidental manner. As my own experience leads me to believe that this is the most important single factor concerned in the death of the fetus during the last three months of pregnancy, I feel that, had we been alive to our responsibilities, we should have had numerous communications concerning the bearing of the discovery of the spirochete and the Wassermann reaction on the validity of the laws of Colles and Profeta, as well as on the practical aspects of prophylaxis and treatment.

In the four groups, including the various phases of labor there were forty articles (*B*), of which five were good and the same number excellent. Most of these dealt with the purely practical aspects of mechanical delivery. On the other hand, no mention was made of our ignorance concerning the causation of labor or of the physiology of uterine contractions, and, although a number of writers dealt with the management of abnormal presentations, only one made a contribution to the mechanism of labor, and another to the anatomy of the parturient soft parts. Did time permit, many other important problems might be mentioned which have been left entirely untouched.

Of the thirty-six articles included in the three groups dealing with the puerperium (*C*), four were creditable and two excellent. Their analysis shows that practically none of the many problems connected with the normal aspects of this period had been considered, and that only two authors had dealt with the fascinating process of involution and then only from a clinical point of view. Furthermore, no one suggested that investigations during this period would probably eventually solve the riddle of the mode of production of retrodisplacements of the uterus and thus do away with one of the opprobria of gynecology.

Careful perusal of the twenty-five papers on puerperal infection indicates very accurately the general point of view of the society. With one exception, no serious contribution to the bacteriology of the affection has been made. The members have been more interested in discussing such questions as whether hysterectomy is the ideal treatment for desperate cases than in studying the mode of origin and the clinical course of the disease in the hope of preventing its outbreak and eventually securing its elimination.

In the four groups dealing with injuries to the birth-canal (*D*), there were three creditable but no excellent papers; little need be said concerning them.

In the seven groups dealing with the various obstetric operations (*E*) there were fifty-five papers, seven of which were good and two excellent. This is a startling disappointment, as it is in just this field that one would expect to find important contributions resulting from American mechanical ingenuity. On the contrary, the papers in this group were unusually poor; most of them consisted of reports of series of cases or of discussions concerning the indications for operation which were devoid of valuable suggestions. That this is not an exaggeration is shown by the fact that only a single paper among the twenty-five on cesarean section presented an idea which was not already well known; while in the articles concerning several other operations suggestions were occasionally made which were at variance with sound practice.

Passing over the two papers on abortion (*F*) we come to the largest group in our analysis, namely, fifty-one papers on extra-uterine pregnancy (*G*), in which there were seven good and five excellent communications. This represents a larger proportion of creditable papers than usual, but I do not think that we obstetricians can take much comfort from the fact, for on looking over the list of authors it is found that the great majority were pure gynecologists, who would feel aggrieved were they accused of having any particular knowledge of obstetrics. Here again most of the papers consisted of casuistic reports, or of discussions concerning the necessity for operation or of details of technic. Several articles were based on experimental work; but, with the exception of the reports on several specimens of ovarian pregnancy, no mention was made of histologic findings, of the interesting variations in placentation, or of many of the important problems connected with the etiology of the condition.

In the group dealing with the toxemias of pregnancy, eclampsia and vomiting (*H*), there were twenty-eight papers, of which three were creditable and two excellent. The same criticism holds good here as elsewhere, for with a few notable exceptions most of the writers were more concerned with the consideration of methods for evacuating the uterus than with the study of the factors responsible for the production of such a condition.

Passing on to the next group (*I*), one is surprised to find that during the course of thirty-eight years a body of obstetricians should have contributed only seven papers dealing specifically with contracted pelvis. On the other hand, this group of papers is unusually meritorious, as two were good and three were excellent. Of course, the subject was also considered incidentally in connection with the various operative procedures; but it seems strange, in view of its great practical importance and of our unsatisfactory methods of diagnosis and classification, that it has not evoked greater interest.

Considering together the three groups dealing with the various types of hemorrhage (*J*), there were twenty-three papers, of which one was creditable and one excellent. The great majority of these communications dealt with placenta praevia and more particularly with the determination of the most conservative method of effecting delivery in the presence of this complication. With but few exceptions, however, I was surprised to find that the experience of the writers on the subject was too limited to permit authoritative conclusions, and that many of the articles consisted in great part of literary references and didactic utterances. As usual, there was but scanty consideration of the mode of causation of the abnormality or of the anatomic peculiarities associated with it. Indeed, the only contribution to the subject was made in the early days of the society.

There were seven papers in the group treating of displacements of the uterus (*K*), the most important of which had to deal with dystocia following operations performed for the relief of retrodisplacements; one of them constituted a real contribution to the subject. In view of the fact that at least one quarter of all women develop retrodisplacements following the first confinement, it appears strange that more attention has not been paid to the etiologic significance of its appearance in the late puerperal period.

In the last two groups, covering the child and the communications on general obstetric topics (*L*), there were thirty papers, which I shall dismiss with the statement that four were creditable, while one constituted a distinct contribution.

Doubtless many of you may consider this analysis a harsh arraignment of the obstetric members of the society, but I feel sure that had it been seemly to mention names and to specify titles many would agree to it, though it is possible that a more lenient critic might have made the list of creditable and excellent papers longer. It is unnecessary for me to state that the analysis was not undertaken in a captious spirit, but was dictated by my interest in obstetrics and by my affection for this society, and in the hope that by laying bare our weak points I may possibly stimulate some of our members to better work.

If my estimate is correct that only twenty-seven of the 346 papers were excellent, the conclusion is inevitable that the American Gynecological Society has not done its part in the advancement of obstetric knowledge. If this is admitted — and I fail to see how any other conclusion can be reached — the query naturally arises whether the failure is to be attributed to the character of our membership or to some more deep-lying factor.

When we canvass the list of members, both past and present, and the important teaching and hospital posts held by them, and also recall the careful scrutiny to which they were subjected before being elected, it must be admitted that with few exceptions the society includes the foremost representatives of American obstetrics. This being the case, it follows that the lack of productiveness cannot be due to failings of the individual members, but should be attributed to some nation-wide cause the explanation of which must be sought in factors peculiar to American conditions.

As far as I have been able to ascertain, only three fundamental contributions to obstetrics have been made by American writers, namely, the introduction of the medicinal use of ergot, by John Stearns; the recognition of the infectious nature of puerperal fever, by Oliver Wendell Homes, and the development of laparo-elytrotomy, by T. Gaillard Thomas — the first a country practitioner, the second an anatomist and litterateur and the third a professor of obstetrics. On the other hand, with few exceptions American obstetricians have been content to appropriate and adopt the results of European investigators and to limit their writings practically to casuistic contributions and to the discussion of details of operative technic.

Opinions may differ as to the national peculiarities which are responsible for this relative sterility, but I feel very strongly that three main factors are involved, namely, (1) the tendency to regard the practice of medicine as an engrossing financial pursuit, (2) defective ideals and tendencies in medical education and (3) the divorce in this country of gynecology from obstetrics.

With few exceptions, all of us undertake the study of medicine as a means of making a livelihood, and consequently, our first aim is to obtain sufficient practical facility in our art to enable us to attain that end, and no one knows better than I what it means to do so and how insistent are the demands of practice. Of those who are exclusively engaged in private practice and who have not formed important hospital or teaching connections, little more can be expected than that they render their patients efficient service by keeping reasonably well abreast with the advance of knowledge and extend a sympathetic hearing to such of their colleagues as may try to add to it.

More, however, should be expected from those who have important hospital connections or who hold teaching posts. The former fail to do their duty to the hospital and its patients if they and their assistants do not attempt to extend the limits of knowledge; while the latter cannot expect to stimulate their students or to train their assistants properly unless they teach them how little is really known and can open vistas of what may be accomplished by patient scientific work. The standing of such men should be judged, not by the size of their income or by the local consideration in which they are held, but by whether they make an occasional contribution to the science which they profess to love, and, if they are content to publish mere casuistic reports or series of operations, they must be prepared to have others consider that they have wrapped their talent in a napkin and buried it.

To my mind, however, one of the most important factors in our lack of productivity is to be found in our system of medical education. Until very recently university ideals were entirely lacking in our medical schools, and even now, in many institutions affiliated with universities, the connection is purely nominal. How many of us who hold professorships can truthfully say that we are held to the same accountability as the heads of the "true" university departments, or are expected to justify our existence by an occasional contribution to science? Do not we, and the authorities as well, consider that our obligations have been satisfactorily fulfilled if we teach a few hours each week, give decent care to the patients under our charge and once or twice a year write a practical paper so that our professional friends may know that we are still alive? We must admit the indictment, but the fault is not entirely ours; for I think that not much more can be expected of us until the universities awake to the fact that medical education is a serious undertaking and is the most costly of all forms of instruction.

How many obstetric departments are provided with proper accommodations for a sufficient number of patients for the instruction of students, with adequately paid and enthusiastic assistants, or with suitably equipped laboratories for research work, not to mention a salary for the director in any way commensurate with the ability and effort necessary to supervise the work in anything like an ideal manner? Real university departments are just beginning to be organized in some other branches of medicine, but I know of none in gynecology or obstetrics.

From extensive investigation I know that, in most of our schools, obstetrics is the department most poorly equipped and must ordinarily be content with what is not wanted by others; often the professor is regarded by his colleagues as being engaged in an almost unworthy pursuit. No doubt some professors are poorly trained and fulfil their obligations lightly, but I know many who take them seriously and feel depressed whenever they consider the status of their department and their inability to do better work. So long as such conditions exist, it is scarcely conceivable that many professors will be scientifically productive or will often be able to induce promising young men to devote themselves seriously to this branch of medicine, for the few men in this country who are really performing their duty are doing so at a great personal sacrifice and against odds with which they should not have to contend.

The third reason for the low state of American obstetrics is that this is the only country in which obstetrics and gynecology are sharply divided, and I may add that this is the only important gynecologic society in which the majority of the members take no interest in obstetric problems, or in which a member discussing a paper would preface his remarks by stating that he knew nothing of obstetrics and then go on to make banal remarks.

Time will not permit me to discuss this phase of the subject at length, but I know that in this country neither gynecology nor obstetrics will take its proper place until a body of men has been developed who will be interested in and devote themselves to the study of the problems connected with the entire sexual life of women. I hope I may live to see the day when the term "obstetrician" will have disappeared and when all teachers, at least, will unite in fostering a broader gynecology, instead of being divided, as at present, into knife-loving gynecologists and equally narrow-minded obstetricians, who are frequently little more than trained man-midwives.

While it is debatable whether a union of gynecology and obstetrics is feasible for those engaged exclusively in private practice or would materially improve matters in most medical schools as at present organized, there is no doubt in my mind that the professorial chairs in the university medical schools need to be filled by broadly trained scientific men, who are prepared to give their time to their duties. Such a development, however, is scarcely to be expected until the universities are prepared to equip and maintain women's clinics, somewhat similar to the Frauenkliniks of Germany, but more liberally provided with laboratories for the anatomic, chemical, pathologic and physiologic investigation of gynecologic and obstetric problems. In this event the director must be an accomplished scientific man as well as a competent clinician, who will devote the major portion of his time to the management of his department. If he is of the proper type, this will involve no sacrifice; but if he is not, he will be unhappy, no matter how great the emoluments may be. Institutions of this character will also require the services of a large staff of well-trained and enthusiastic assistants, but will be able to make little use of the short-term intern, who desires only a smattering of learning. Large endowment or state aid will be necessary for the support of such institutions, but I can conceive of no better expenditure of funds if it leads to fuller knowledge of the many unsolved problems connected with women and to the development of a body of men competent to undertake their investigation.

I hope to see a number of such institutions scattered over the land and then no future president of this or any other society will be able to say that its members have not done their part in the advancement of obstetric or gynecologic knowledge. We have heard of "the passing of a specialty," but I feel that there is a glorious future for the broader gynecology, which is as yet scarcely in its infancy. Let us do what we can to advance it.

Hygiene and School Instruction.—The text-books offer a splendid field for instruction, and the time is not far distant when those classics in school literature, "Ned, can you hop?" and "What is in the nest?" will give way to epigrammatic statements concerning the value of fresh air, the danger of the common drinking-cup and the roller towel, the importance of a pure water-supply, the relation between sewage and disease, the contributing influence of alcoholic indulgence in the development of tuberculosis, etc.—J. H. Landis, in *Am. Jour. Pub. Health.*

TYPHOID FEVER *

EDWIN O. JORDAN, PH.D.
Professor of Hygiene and Bacteriology, University of Chicago
CHICAGO

Typhoid fever does not originate by itself, out of a clear sky. Everybody knows that it is possible to connect many typhoid cases with a previous case of the same disease. This would be true of every case if we could discover all the circumstances of infection.

Like all other infectious and contagious diseases, typhoid fever is a germ disease, that is, it is due to a small living organism. The typhoid germ does not develop by "spontaneous generation" out of lifeless matter, nor does it come into existence suddenly as the wayward offspring of an innocent microbe, but only as the descendant of another germ of the same kind. It is therefore true that if all typhoid germs now living could be destroyed, the disease itself would cease to plague us. Although immediate and complete extermination of all typhoid bacilli is an impossible task, it is evident that if we can in any way materially lessen their number, we shall also diminish the frequency with which infection occurs. One rattlesnake in a town is less dangerous than ten thousand rattlesnakes. In this sense typhoid fever is a preventable disease. If we can keep away from the typhoid bacillus or can keep it away from us, we shall not have typhoid fever. We cannot see the bacillus without a microscope, but fortunately we know where it lives and how we are likely to come into contact with it, so that we are able to do much to protect ourselves.

First of all we must remember that typhoid fever is a disease restricted to man. None of the domestic animals suffer from it. In consequence, methods of prevention are in some respects simpler than in the case of a disease which, like tuberculosis, afflicts animals associated with man as well as man himself.

EARLY RECOGNITION OF TYPHOID FEVER IMPORTANT

For purposes of prevention as well as cure it is important to recognize the existence of typhoid fever in an individual or in a community as early as possible. The symptoms of typhoid fever, like those of other infectious diseases, are not the same in all persons. Atypical cases are often encountered in epidemics. There are all grades of severity, from the extremely toxic and fatal cases to those in which the patient thinks he is suffering merely from a slight "indisposition" or "bilious attack," is able to keep about his work and perhaps never calls in a physician. Even in severe cases some one or more of the usual symptoms of typhoid fever, such as initial headache, rose-spots over the body, characteristic fever curve, or enlarged spleen may be lacking, or the disease may present an unusual and confusing symptomatology so that early diagnosis is uncertain or impossible. It is less than a hundred years since typhoid fever began to be distinguished by physicians from other "slow" or "continued" fevers, and there is still a measure of uncertainty in some cases in which physicians have to base their diagnosis on "symptoms" alone, and have not the aid which comes from the laboratory tests. Infection with the typhoid bacillus may be mistaken for malaria or for infections with other bacteria, such as the tubercle bacillus. From the point of view of prevention it is highly important that diagnosis of typhoid fever be made as early and as accurately as possible in order that suitable means shall be taken to prevent further dissemination of the typhoid bacilli from the sick person.

At present the physician can avail himself of two valuable diagnostic procedures in addition to a study of the symptoms. One of these is examination of the blood by means of cultures. The typhoid bacillus is present in the circulating blood early in the course of the disease, so that from 20 to 40 drops of blood, drawn from the ear or finger or, better, from a vein in the arm by means of a sterile syringe and subjected to expert bacterial cultivation and examination, will reveal the presence of the typhoid bacillus usually in the first week of the disease. If the blood is examined later than the first week or ten days, even in pronounced cases the bacilli may not be found. When the typhoid bacillus is actually obtained from the blood in this way there can be no further doubt as to the presence of typhoid fever. A certain degree of technical experience and suitable laboratory facilities are necessary for the proper application of this method.

The other method of bacterial diagnosis is the agglutination or Gruber-Widal test. This is based on the discovery that the blood of persons who are infected with the typhoid bacillus possesses the power of clumping or agglutinating the bacilli. For this test there is needed only a small amount of blood, which may be collected in small tubes, or allowed to dry on mica slips. When the serum from a drop of coagulated blood is mixed in dilution of 1:50 or, better, 1:100, with a culture of typhoid bacilli suspended in salt solution, the bacilli will gather in clumps if the blood is taken from a typhoid fever patient, but will remain separate if the blood comes from a normal person or from one affected with a disease which is not typhoid fever. This clumping property in the blood does not develop as a rule until the second week of the disease, and may not appear until later, or may be absent altogether in exceptional cases. It is so often positive, however, even in cases in which other symptoms are obscure, that it has proved a very valuable aid in typhoid diagnosis. The presence or absence of agglutinative power cannot be regarded as final, but taken along with the clinical symptoms and other circumstances it makes it possible for physicians to recognize the existence of typhoid infection in practically all cases. If the first agglutination test is negative, and the symptoms of typhoid persist, a second and even a third test should be made. In the interpretation of positive agglutination tests, careful inquiry should be made as to previous typhoid infection or previous typhoid vaccination, since in either of these instances a positive agglutination may be obtained although the disease from which the patient is suffering may be due to other infection. Moreover, either typhoid vaccination or a previous attack makes the subsequent occurrence of typhoid extremely unlikely.

The importance of recognizing as many cases of typhoid fever as possible and recognizing them early is very great. The typhoid germ multiplies almost exclusively in the living human body and cannot as

* This paper is one of a series on Public Health, prepared at the request of the Council on Health and Public Instruction, and reprinted for distribution to the public through state boards of health and other agencies. Other articles are being prepared and will be issued later. A list of the pamphlets can be secured from the Council on Health and Public Instruction, American Medical Association, 535 North Dearborn Street, Chicago.

a rule retain its vitality very long apart from its human host. The disease is kept alive, therefore, mainly by the transfer of the living germ from the person in whom it has grown, usually a typhoid patient, convalescent, or carrier, to a healthy person who gives it shelter, becomes a breeding-ground for it, and in his turn passes it on to one or to hundreds of others. It is one of the urgent tasks of public hygiene to break this chain of typhoid germs at as many points as possible.

REPORT TYPHOID CASES

To this end it is necessary to establish in each community or group of communities some central health office to which the physicians shall report every case or suspected case of typhoid fever coming under their observation. Only in this way can the beginnings of an epidemic be detected and measures taken to prevent further spread. One or two typhoid cases in the practice of a busy physician naturally do not appear to him especially significant, but if several physicians report cases occurring about the same time so that the total number in the town is suddenly increased to an unusual degree, the health authorities are at once made acquainted with the situation and can try to discover the source of the outbreak. Only in this way, too, is it possible to place each case of typhoid fever under the centralized supervision that it must have in order to lessen the chance of further scattering of disease germs throughout the town. Family and friends must be warned of the danger of close association with the patient. In some instances in which expert nursing cannot be provided, special precautions must be taken to insure the disinfection of the excreta. For all these reasons it is easy to see why prompt notification of every suspected case of typhoid fever is the first important step in preventing spread of the infection.

WHERE THE TYPHOID BACILLUS IS FOUND

While the typhoid bacillus makes its true home in the human body and does not thrive in water, soil or the bodies of the lower animals, it is nevertheless able to survive for a few hours or days after it leaves the body of its host. This fact explains why typhoid fever is sometimes caused by germs that have traveled many miles away from the person in whose body they originally grew. Typhoid bacilli are discharged from the body in (1) the feces, (2) the urine and rarely (3) the sputum. They may be present in these excretions in enormous numbers. A single drop of urine may contain as many as one million living typhoid germs. Clothing, bedding, table utensils, in fact any object used by, or coming into contact with, a typhoid patient may easily become contaminated with typhoid bacilli even when ordinary care is used. It has long been known that members of the family and especially those nursing typhoid patients are very liable to contract the disease. Any one can see why this is so. Merely swallowing the typhoid germ is sufficient to produce typhoid fever. The facts just stated show how difficult it is to avoid swallowing typhoid bacilli whenever persons must live for days or weeks in close association with a patient who may be discharging daily hundreds of millions of germs. Ordinary washing or rinsing of the hands does not render them bacteriologically sterile. The attendant of a typhoid patient, after going to the sick-room or handling anything from it, should wash the hands thoroughly with soap and water and, if possible, use also a disinfectant solution such as 1:2,000 mercuric chlorid, compound solution of cresol, or 70 per cent. alcohol. Towels, door-knobs, articles of furniture or clothing may be the means of conveying typhoid bacilli to the hands. The hands may in turn be used for breaking or handling bread, cake or other articles of food and so introduce typhoid bacilli into the mouth. Contact infection, or more appropriately hand infection, is one of the most common causes of typhoid fever, and close association with typhoid patients must always be looked on as dangerous. The danger can be reduced by removal of typhoid patients to the hospital. Unskilled home nursing, however painstaking and affectionate, will always imperil the household. This is particularly the case if the person caring for the patient also has to do with the preparation of food for other members of the family. Even in hospitals, experienced nurses and attendants are likely to contract the disease unless great care is taken. All nurses of typhoid patients and all persons living in houses in which typhoid patients are being cared for should be protected by the method of typhoid vaccination which will be described presently.

WATER-BORNE INFECTION

The direct handing over of typhoid germs from one person to another which has just been described is only one way in which the disease is transmitted. The mode of infection may be much more indirect and roundabout. Typhoid bacilli sometimes find their way into food or drink used by large numbers of persons and give rise to explosive and very extensive outbreaks. Public water-supplies and milk-supplies are two of the most common sources of typhoid infection. In many localities the connection between water-supply and sewerage systems is far too close. The enormous amount of water required for large cities in this country can seldom be obtained absolutely free from sewage contamination. When typhoid germs leave the body in the excreta they are likely to pass into the sewerage system.[1] It does not take a large quantity of sewage to produce infection. The discharges of a single patient, even when diluted with several million gallons of water, have been known to give rise to over one thousand cases of typhoid fever. This is not so remarkable as it seems if we remember that the number of typhoid bacilli discharged in one day may easily reach 5,000,000,000, or more than ten germs in every gallon of water in a large supply like that of Chicago.

Surface water-supplies such as rivers and lakes are especially liable to sewage contamination, and with the growth in density of population in this country such pollution seems likely to increase rather than diminish. Under present conditions all sewage must be regarded as possibly containing typhoid germs. In many localities it is not considered practicable to render sewage entirely free from intestinal bacteria before its discharge into large lakes or water-courses. Water-supply officials are hence right in advocating purification of all water-supplies not obtained from perfectly pure sources. Purification and consequent freedom from disease germs may be secured either by filtration on a large scale or on emergency by treatment with calcium hypochlorite (bleaching-powder). Even carefully protected water-supplies from thinly settled districts are liable to accidents. In Germany this is recognized to the extent of requiring the purification of all surface waters used for city supplies.

---

[1] It might be supposed that if all the excretions from typhoid patients were sterilized the disease would cease to exist, and it is undoubtedly true that the prevalence of the disease would be greatly diminis[illegible] typhoid excreta were more generally [illegible] matter is not quite so simple. Besides [illegible] already mentioned which never come under the care of a physician, and the irregular cases which are not definitely recognized as typhoid, there are some convalescents who continue to discharge living and virulent typhoid bacilli from their intestines long after complete recovery has taken place. In addition there are certain patients, probably rather numerous, who have begun to discharge typhoid bacilli in the feces before typical symptoms have appeared and before they have submitted themselves to the care of a physician. Even with the great improvement that would come if the disinfection of the excreta of all known typhoid patients were strictly carried out, those persons in the groups just described would be sufficiently numerous to propagate the disease. All sewage must be regarded as infectious.

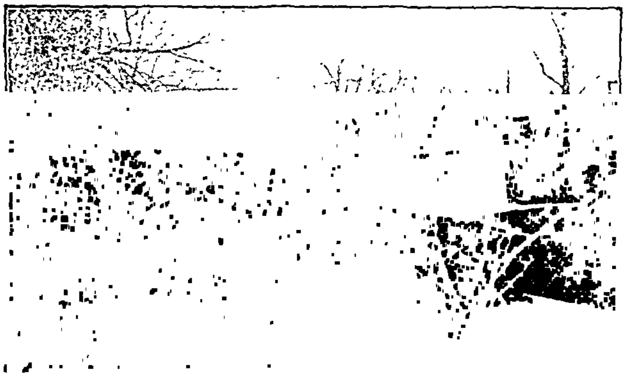

Fig. 1.—This reproduction of a photograph shows a privy overhanging a small brook, one of the feeders of the Merrimac River, Massachusetts, only 2½ miles above the intake of the Lowell water-works. The privy was used in October, 1890, by a patient in the beginning stages of typhoid fever. The use of this outhouse by the patient was followed by an outbreak of typhoid fever in Lowell, numbering several hundred cases. (From Sedgwick's Investigations of Recent Epidemics of Typhoid Fever in Massachusetts, 1892.)

In country districts, also, water may be a vehicle of typhoid infection. Wells so placed as to receive drainage from privies are a source of danger. In limestone regions the beautiful but treacherous "springs" need to be examined with special care, since the so-called springs are often only small surface streams and brooks which emerge at the surface after a longer or shorter flow through underground channels. If seen in the beginning as a brook the water would be recognized by every one as coming from dangerous localities, while as a "spring" it might be drunk without suspicion of its filthy origin.

Deliberate water-drinking is not the only way in which typhoid fever may be contracted from polluted water. It must be remembered that while bathing in polluted water, either salt or fresh, one may accidentally swallow small quantities of water, and this has been known in a number of instances to give rise to typhoid fever.

Measures to prevent the spread of typhoid fever by means of water-supply may be summed up as follows: Our first endeavor should be directed to preventing in every way possible the entrance of typhoid germs into sewers or into privy vaults. To this end, thorough disinfection of all discharges from the body of a recognized typhoid patient must be carried out.[2] In spite of all precautions some typhoid bacilli will get into the sewage,[1] and hence such sewage must be always regarded as probably infective. Sewage should be kept out of all water sources used as drinking water-supplies. All of the usual methods of treating sewage such as sedimentation, precipitation, filtration, and the like diminish the danger of water-borne typhoid fever even if they do not altogether remove it. A more effective barrier against typhoid bacilli in water is the purification of the water-supply itself by storage, filtration or treatment with bleaching powder. Finally, if municipal methods are inadequate and there is reason to fear that typhoid bacilli sometimes get into the water-mains, security against water-borne infection may be obtained in the household by boiling the water for five minutes.

In the country the purity of the drinking-water rests largely in the control of each family. Shallow wells should be protected against surface wash and should be so located that the contents of privy vaults and outhouses can by no possibility leak through the soil into the well-water. Deep driven wells protected from surface contamination constitute a particularly safe source of supply.

MILK-BORNE INFECTION

Milk, like water, can be the means of introducing typhoid bacilli into the body. Several hundred well-marked epidemics of typhoid fever are on record which have been traced to milk containing typhoid germs. The bacilli may get into the milk in various ways. When a person suffering from a mild or unrecognized case of the disease is engaged in the collection or distribution of milk, or when flies have access to the contents of a privy vault in which typhoid bacilli happen to be present and at the same time have access to the milk-house, or when milk-cans or bottles are rinsed in impure water just before filling, or are not sterilized after removal from a house in which typhoid fever prevails, the possibilities of infection are clear enough. Unlike water, milk may serve as a medium for the multiplication of typhoid bacilli so that a small amount of infected milk mixed with other milk at a creamery may lead to the distribution of many more bacilli than were originally present. Such multiplication probably goes on for only a limited period while the milk is still quite fresh. The danger of infection from buttermilk or from butter made from sour cream is much less than

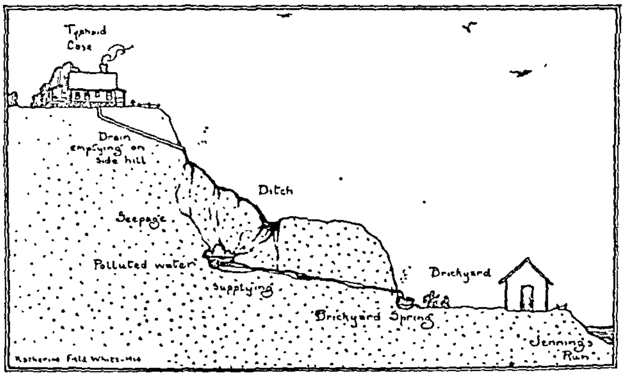

Fig. 2.—The spring at the brickyard furnished an abundant supply of clear water "of pleasant taste and appearance and agreeable coolness." Following the development of a typhoid case in the cottage on the hill, 108 of the 200 workmen in the brickyard became ill with typhoid fever. (Adapted from a study of an epidemic in 1906 at Mount Savage, Md., by Stokes and Price, Maryland Med. Jour., December, 1906.)

---

[2] Typhoid stools may be disinfected by adding enough hot water to cover the stools in the receptacle together with about a cupful of commercial unslaked lime (quicklime). The lime should be in lumps, broken up in small pieces and distributed over the stool. The mixture should stand for two hours. Chlorinated lime (¼ pound in 1 gallon of water) solution can also be used.

from fresh milk. Protection against milk-borne typhoid may be easily secured by boiling or pasteurizing all milk not known to be safe. Typhoid bacilli are killed by exposure for ten minutes to a temperature of 60 C. (140 F.), so that efficient pasteurization constitutes an excellent safeguard. It is plain also that milk should not be distributed from farms on which typhoid fever exists, and that on all dairy farms human excreta should be regarded as highly dangerous and should be disposed of with particular care.[3]

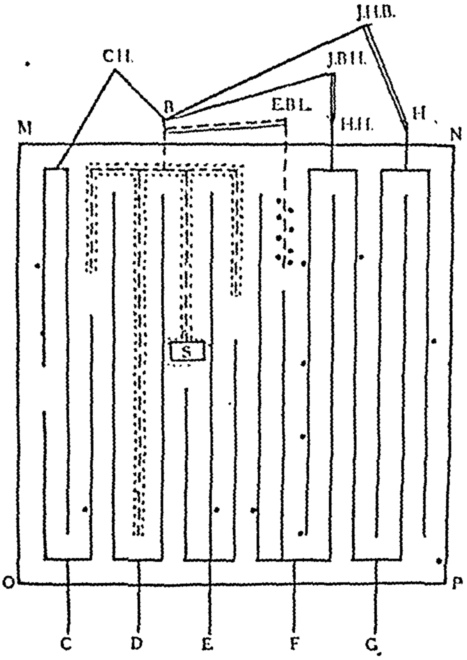

Fig. 3.—Stamford typhoid fever epidemic, April 15 to May 28, 1895 (Herbert Smith: Connecticut State Board of Health Report, 1895, p. 161). Stamford had a population of 15,000. The large square *M N O P* represents the town of Stamford. *B* is the dairy distributing the implicated milk, and the dash-lines running from *B* into the city represent the milk-route of the dairy. Each of the dots represents one case of typhoid fever, and is placed on the route of the dairy from which it was supplied with milk. There are 368 such cases on *B's* route, including the 12 around the *S*, which is meant to represent the café supplied by *B*. *B* supplied about one-eleventh of the milk used in the town. *HH* and *H* are distributing dairies similar to *B*. *CH* and *EBL* are producing farms selling milk to *B* and also peddling some themselves. The dash-line extending from *EBL* represents his personal route of 5 houses in which 8 cases of typhoid occurred. *JHB* and *JBH* are producing farms selling milk to *B* and also to distributing dairies *H* and *HH*. The double lines show the dairy to which the producer sold most of his milk. Dash lines show the apparent course of the infective agent. *C, D, E, F,* and *G* are other dairies having routes in Stamford.

TYPHOID FROM OTHER RAW FOODS

Besides milk some other articles of food seem particularly exposed to possibilities of typhoid contamination. Oysters and other shell-fish that have grown in sewage-contaminated waters or that have been placed to "fatten" by "floating" or "drinking" near the mouths of sewage-polluted creeks have been shown to harbor the typhoid bacillus, and when eaten raw to produce more or less extensive typhoid outbreaks. Thorough cooking of shell-fish does away altogether with the possibility of infection through this source. In the United States, inspection and control of oyster beds by state and national health authorities have greatly reduced the possibilities of danger from the use of raw oysters. Certain vegetables or berries commonly eaten uncooked may become contaminated with typhoid bacilli if night-soil is used as a fertilizer on truck gardens, or if raw sewage is used for irrigation. The use of human excreta as fertilizer for certain crops, such as celery, lettuce, or strawberries, is most undesirable. In a few instances definite outbreaks of typhoid fever have been shown to be due to the use of raw vegetables or fruits. The difficulties in the way of tracing infection to the use of such articles are plainly very great, and many investigators are of the opinion that a larger amount of typhoid fever is due to the use of contaminated raw foods than can at present be actually proved.

FLY-BORNE INFECTION

Under conditions in which human excreta are exposed to the visits of house-flies, the possibility of spreading infection through the agency of these insects is well recognized. Back and forth from privy vault to eating-table wander these bearers of infection. At the time of the Spanish-American War when lime was used in the camp latrines, flies with their legs whitened with lime were afterward seen walking over the food on the mess-tables. Conditions favoring fly-borne typhoid fever are especially favorable on the farm as well as in military encampments, lumber or construction camps, and the like. Reduction in the number of the flies, which can be effected especially by elimination of their breeding-places, of which horse-manure is one of the most common, together with proper disposal of excretal refuse, will greatly diminish if not altogether remove danger from this source. A room or hospital ward containing typhoid patients should be carefully screened in fly-time. It must be remembered that the fly can act only as the mechanical carrier of typhoid bacilli. However disgusting and annoying the fly's habits may be, if it does not have access to material in which typhoid bacilli are present, it cannot convey typhoid fever.

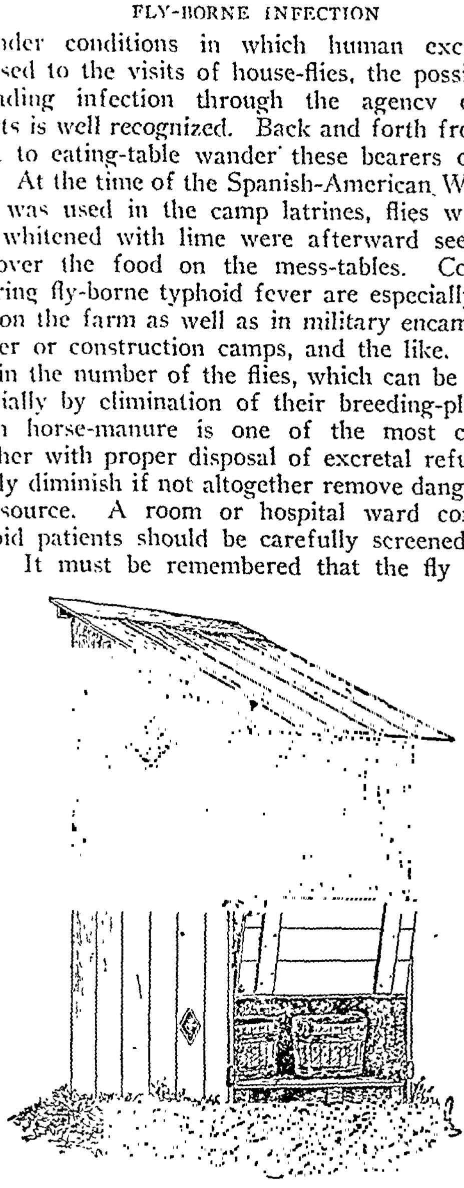

Fig. 4.—This sanitary privy with raised back is fly-tight and is so arranged that the buckets or tubs within do not touch the ground. (From the Virginia Health Bulletin, June, 1911.)

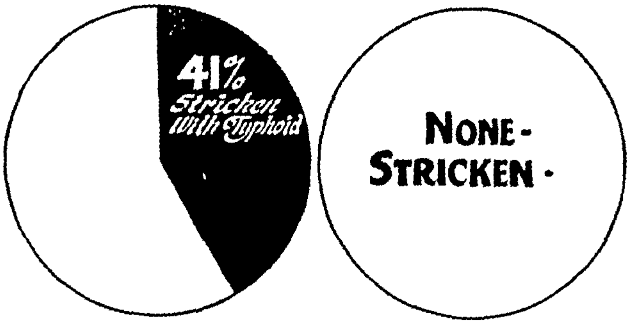
---

[3] A simple and inexpensive sanitary privy adapted for use on the American farm is described in a bulletin of the United States Department of Agriculture. This bulletin (Farmers' Bulletin 463), may be obtained free of cost from the State Board of Health or from the Department of Agriculture, Washington, D. C. It gives full working directions for the construction of the sanitary privy.

There is no evidence that typhoid fever is ordinarily air-borne. Under unusual conditions it is possible that dried excreta might be blown about as "dust" and that typhoid bacilli might then come to settle on food or possibly even be inhaled and swallowed, but this mode of infection is probably very rare. The immediate neighborhood of a typhoid patient is dangerous not because there are any typhoid bacilli floating in the air, but because of the likelihood that objects in the room—pillows, arms of chairs, doorknobs—have been accidentally contaminated in the care of the patient.

TYPHOID CARRIERS

The fact has already been mentioned that well-defined and active cases of typhoid fever are not the only ones that may be discharging typhoid bacilli. The importance of healthy typhoid carriers needs to be still further emphasized here. Recent investigations have shown that from 4 to 6 per cent. of all persons recovering from typhoid fever continue to discharge typhoid bacilli in the feces or urine or both for months and even years after complete recovery. Occasionally, also, a person who has never had a recognized case of typhoid is found to be a carrier. Plainly, such persons are likely to be starting-points of fresh infections, especially if, as in the famous case of the New York cook, "Typhoid Mary," their occupation is concerned with the handling or preparation of food. "Typhoid Mary" was the cause of twenty-six cases of typhoid among the members of seven different families for whom she worked.



Jacksonville, Fla., 1898; Seventh Army Corps, U. S. Army; 10,759 men, none given typhoid vaccine.

U. S. Army, San Antonio, Tex., 12,801 men, all given typhoid vaccine.

Fig. 5.—Results of typhoid inoculation. (From Washington State Board of Health Bulletin, May, 1912.)

An undetected carrier on a dairy farm may be the cause of an explosive outbreak, or of scattered cases along the milk-route during a considerable period. No satisfactory means have yet been found for permanently ridding these typhoid carriers of the germs that they harbor. Carriers, when found, must be warned of the possible havoc they may scatter among relatives and friends, and so far as possible should be prevented from engaging in occupations which involve a maximum hazard to the community. Since the number and identity of such carriers in a community are at present not readily ascertainable, all sewage and the contents of all privy vaults must be looked on as possibly infectious. The chance use by a visiting typhoid carrier of an improperly constructed outhouse in a small country town or on a dairy farm may be the starting-point of a serious outbreak whose origin will always be "mysterious." While the problem of dealing with typhoid carriers is very difficult, it cannot be forgotten that the outlook in general is a very hopeful one. Any diminution in the number of water-borne or milk-borne epidemics will avoid the production of new carriers. The improvement is bound to be progressive. Every reduction in the amount of typhoid fever automatically lessens the number of carriers.

It can be seen from the foregoing that improper disposal of excretal refuse is at the bottom of most typhoid fever infection. Particularly is this so in country districts, where fly-borne infection is most likely to take place, and where the bulk of milk infection, from which city dwellers later have to suffer, also occurs.

TYPHOID VACCINATION

It has been found that injection of killed and harmless typhoid bacilli will protect against typhoid infection even in persons particularly exposed by their occupation or other social conditions. In the United States Army, in which typhoid vaccination has been compulsory since September, 1911, the disease has practically disappeared. In 1909 there were 173 cases and 16 deaths in a force of about 69,000 men; in 1912, only 27 cases and 4 deaths in about 83,000. From August, 1912, to August, 1913, there were only 2 cases. Many of these troops were engaged in maneuvers in Texas (1911-1912) and were associated more or less intimately with the civil population, among whom typhoid cases were occurring in considerable numbers. Owing to the conditions under which soldiers must live in the field or on the march, the likelihood of typhoid fever is great. In 1898 at the time of the Spanish-American War, 4,422 cases of typhoid and 248 deaths occurred in a division of 10,759 men; among 12,801 vaccinated men under very similar conditions at San Antonio, Tex., in 1911, only one case developed.

Similar results have been obtained in hospitals in which typhoid patients are cared for and in which in the past many cases have developed among the nurses. In one large hospital inoculation of the nurses was followed by a year of entire freedom from the disease among nurses and attendants for the first time in the history of the institution. The lesson is plain. All persons whose occupation tends to expose them to typhoid infection should be vaccinated. Nurses, physicians, soldiers and all those whose manner of life leads to frequent travel and to eating in a variety of restaurants, hotels, or to drinking of water of unknown source come under this head.

What is commonly known as "vacation typhoid" is chiefly the typhoid picked up by contact with infection during travel. In a word, the larger the number of places to which one resorts for food and drink the greater is the chance of crossing the trail of a typhoid carrier. Vaccination gives a high degree of protection for three years, perhaps for a longer period. For those who are not directly exposed to known typhoid infection, but who realize the possibilities of infection through intercourse of urban life, typhoid vaccination, which has been clearly shown to be both safe and efficient, offers an attractive and cheap form of insurance against typhoid fever.

RULES FOR PREVENTING TYPHOID FEVER

For the Individual:

1. Keep away from all known or suspected cases of typhoid.

2. Wash hands thoroughly before meals. Do not use "roller towels."
3. Use drinking-water only from sources known to be pure, or if this is not possible, use water that has been purified by municipal filtration or by hypochlorite treatment or by boiling in the household.
4. Avoid bathing in polluted water.
5. Use pasteurized or boiled, instead of raw, milk.
6. Select and clean vegetables and berries, that are to be eaten raw, with the greatest care.
7. Avoid eating "fat" raw oysters and, in general, oysters and other shell-fish whose origin is not known.
8. Be vaccinated against typhoid in all cases in which any special exposure is known or feared.

For the Community:

1. Insist on the hearty cooperation of all persons with an efficient health officer.
2. Require notification and a reasonable degree of isolation of every known or suspected typhoid case.
3. Exercise strict control over the disinfection of known typhoid excreta.
4. Insist on pure or purified water-supplies.
5. Require pasteurization of milk-supplies.
6. Regard all human excreta as possibly dangerous, and control their disposition in such a way as to prevent contamination of food or drink.

THE PREVENTION OF SURGICAL SHOCK AND POSTOPERATIVE PAIN *

A. B. COOKE, M.D.
LOS ANGELES

Differ as we may as to the real nature of surgical shock, the exact factors concerned in its production and the various intricate physiologic and biologic problems involved, no one will deny that it constitutes the greatest danger of modern surgery. Certainly no more important subject can engage our thought and effort than to prevent it, or at least to minimize it, as far as possible, in every case. It is equally true that the prevention and minimizing of postoperative pain are questions which command the unfailing interest of every physician who is imbued with the true spirit of his calling. Various theories have from time to time been advanced as to the cause of shock, each one containing an element of truth, but no one of them containing the whole truth. Generally operators of large experience tend to regard surgery as merely routine daily work and to give their attention rather to the pathology involved and the mechanical execution of a predetermined procedure, than to the philosophic and the humanitarian considerations relating to the subjects on whom their skill is expended. When one stops to consider the disproportionate importance which comes to be attached to the operation itself, there is little wonder that such divergent theories are held. True, surgical shock is frequently encountered, but only an occasional patient succumbs to it. True, postoperative pain is a distressing sequel in practically every case, but pain does not kill and the patient ultimately forgets. In the satisfaction of having performed a brilliant and mechanically perfect operation, the busy surgeon is apt to regard shock and pain as minor considerations and complacently to felicitate himself and his patient on the final happy outcome. They are *not* minor considerations. To the patient at least, a surgical operation is always a formidable ordeal and he has the right to demand that he shall be safeguarded in every way possible from both danger and pain. Surgery does not fulfil its highest mission unless the welfare of the patient is at all times recognized as paramount to operative technic, though to keep it so requires a little extra time and a little additional trouble on the part of the surgeon, as well as some increase in the incidental expense.

It is the consensus of opinion to-day among both clinicians and laboratory workers that the loss of vasomotor control resulting in the reduction of the blood-pressure below safe limits is the chief factor in the production of shock. The question before us, then, is: How may a surgical operation be conducted so as to cause the least possible disturbance of the vasomotor function? I am convinced that the method of anoci-association, as worked out by Crile, offers the best means yet devised to accomplish this end. At the same time it possesses the distinct additional advantage of protecting the patient against postoperative pain.

It seems almost superfluous to say that Dr. Crile fully recognizes the importance of complete hemostasis and of expedition in operating. Being a most painstaking and notably dextrous operator himself, he regards these as elementary surgical principles. He does not hold, however, that five or ten minutes' additional time properly utilized in the average operation is criminal practice. Haste means roughness of manipulation and he emphasizes gentleness as a primary requisite to the successful employment of the method which he advocates.

THE PRINCIPLES OF ANOCI-ASSOCIATION

The four cardinal principles of anoci-association are:

1. The preliminary administration of a hypodermic of morphin and scopolamin.
2. The use of nitrous oxid and oxygen for general anesthesia.
3. The complete blocking off of the operative area by the infiltration of a solution of novocain.
4. The infiltration of all tissues traumatized which are supplied with sensory end-organs (except the skin) with a solution of quinin and urea hydrochlorid.

To these I would add a fifth, referring especially to the prevention of gas pains following abdominal operations, namely, early opening of the bowels.

1. The preliminary hypodermic of morphin and scopolamin is designed to allay apprehension and tranquillize the patient. In certain cases the psychic factor is quite as important as the physical. In all cases the preoperative management calls for far more care and attention than it usually receives. An attitude of calm decision and confidence on the part of the surgeon and of cheerful sympathy and encouragement on the part of the nurse do much to rob the coming ordeal of its terrors. The hypodermic consisting of morphin sulphate 1/6 grain and scopolamin 1/150 grain should be administered an hour and a half in advance of the operation and repeated an hour later in half the dosage, if the desired effects, that is, sleepiness and relaxation, are not obtained. Complete quiet in and about the operating-room should always be insisted on, at least until the patient is anesthetized.

---

* Read before the Los Angeles County Medical Society, April 2, 1914.

2. It is universally conceded that, in competent hands, nitrous oxid is preferable to ether for general anesthesia, even in face of the fact that it possesses certain inherent disadvantages. Ether is irritating and malodorous, and by the resistance it arouses in the primary stage (so-called stage of excitement) favors the development of shock. It immediately and definitely impairs the defensive powers of the patient. It lowers the blood-pressure much (two and a half times) more quickly and decidedly than nitrous oxid. The changes in the brain-cells are three times more marked under ether than under nitrous oxid, because oxidation is retarded by the latter anesthetic. Ether increases the coagulation time of the blood. It is a powerful solvent of the body lipoids, kidney, liver and other viscera, as well as the brain, and in consequence there is always a large increase in the amount of waste products to be eliminated thereby favoring the development of nephritis, pneumonia and other postoperative complications. The nausea and vomiting incident to ether anesthesia are both distressing and dangerous.

Nitrous oxid is not unpleasant to take; it induces anesthesia almost at once, and the effect passes off as quickly as it is produced. Properly combined with oxygen and administered by a skilled anesthetist, it is now regarded as safe as ether, even for prolonged operations — far safer when the possible and not uncommon sequelae of ether anesthesia are taken into account. The anesthesia produced by nitrous oxid is not so deep and death-like as that produced by ether; but this is rather an advantage, since it necessitates thoroughness in the technic of the accompanying local anesthesia and demands gentleness of manipulation at every step of the operation.

The disadvantages of nitrous oxid are physical and financial rather than clinical. The apparatus required is cumbersome and costly and the gas itself is expensive. But these are negligible items when compared with the positive benefits it offers; and neither the surgeon nor the hospital is justified in declining to provide anything and everything which will make for the safety and comfort of the patient.

3. The combination of local with general anesthesia may be termed the crucial feature of anoci-association. It is based on the hypothesis that, however profoundly the patient may be under the influence of an inhalation anesthetic, the brain-centers are still capable of receiving impressions from peripheral stimuli and the brain-cells still capable of liberating impulses in response, otherwise the patient would be dead instead of merely unconscious. The only way by which this connection may be broken is by blocking off the area to be traumatized with a quickly acting, non-toxic local anesthetic. Novocain in 0.25 per cent. solution is the agent employed. First the skin in the line of the proposed incision is carefully infiltrated and then the subjacent tissues step by step as they are encountered. The application of pressure renders the anesthetic effect practically instantaneous. When the abdominal cavity is to be opened the peritoneum should first be thoroughly infiltrated in the line of the incision and the edges everted and blocked off for an inch on either side to protect it in the further manipulations. Complete relaxation is the gauge of thoroughness. If the technic is properly carried out, an incision in the upper abdomen may be approximated and closed with as great facility as one in the lower abdomen.

The benefits of the local anesthesia may and should be extended to the internal organs whenever indicated. Many viscera are unprovided with sensory nerve terminals and, if handled gently, may be operated on with impunity without the use of the local anesthetic. For instance, it is entirely possible in the absence of undue traction to perform the visceral suturing in a gastro-enterostomy without the least disturbance, even when the general anesthetic is suspended. On the other hand, certain of the internal organs, notably those of the pelvic cavity, have an abundant sensory nerve-supply and should be as carefully blocked off before proceeding with the operation as was the region of the initial incision. In a hysterectomy, for example, infiltration of the round ligaments and of the tubes and broad ligaments at the points to be sectioned should first be carefully made and then extended to the peritoneal folds in front of and behind the uterus as these structures become accessible. The appendix may be blocked off by infiltrating the meso-appendix and likewise the base of the gall-bladder and other areas as indicated.

4. The anesthetic effect of quinin and urea hydrochlorid is maintained for from forty-eight to seventy-two hours; that of novocain is quite transient. This in brief is the explanation of the fourth principle of anoci-association. Before closing the wound all stumps containing sensory nerves are infiltrated with a 0.25 to 0.5 per cent. solution of the quinin salt and the several tissues of the wound itself similarly treated as was the case with the novocain solution in making the incision. By this means the parts are held anesthetic until the process of repair is established and the patient escapes much of the customary postoperative discomfort.

Objection to the use of this agent is sometimes made, doubtless will be on this occasion, on the ground that it is dangerous, that it often causes necrosis, etc. In the light of my personal experience I can only say that such dangers are purely imaginary. If the solution is used in proper strength and the technic of its employment is correct in every detail, there is no ground for apprehension. Of course it must be recognized that the salt is a chemical irritant, and the man who injects a 4 per cent. solution into the skin and subcutaneous tissues is likely to meet with disaster. The slight edema sometimes noticed in the wound area after the use of the weaker solution is of no consequence and in no case coming under my observation has it seemed in any way to interfere with the healing.

It will be recognized at once that the successful employment of the novocain and quinin and urea hydrochlorid solutions requires a dexterity and a familiarity with the technic of local anesthesia which is not acquired without considerable experience. The degree of local anesthesia demanded in this technic is as complete and perfect as though no other means were used. No man not accustomed to operating under local anesthesia can expect to make a brilliant success of his first case, nor indeed of his first half dozen cases. On this point Bloodgood[1] remarks:

> It is important, in the first place, to emphasize here that success depends most perhaps on the technic of local infiltration. No surgeon who has not performed many operations under local anesthesia only, will be able to get the same results from the combined method. When the patient is awake and you attempt an operation under local anesthesia, you will always be informed when a painful act takes place and you

---

[1] Studies in Blood-Pressure, Ann. Surg., December, 1913.

will be surprised at the difficulty of making such an operation perfectly painless. Very few surgeons in this country have educated themselves in the difficult technic of local infiltration. They are not familiar with the sensitiveness of the different tissues and the varying degrees of discomfort following different manipulations. It is my opinion that the first step in the development of this new technic is to perform as many operations as possible under local anesthesia.

With reference to the securing of early bowel-movements as a means of preventing gas-pains in abdominal surgery, which I have presumed to suggest as a fifth important step in the technic of anoci-association, let me say that my own experience has borne out the wisdom and beneficence of this plan in a long series of cases. Before adopting Crile's technic it had been my custom for a number of years to start the process of alimentary elimination on the second day following all abdominal operations unless some positive contra-indication existed. And I have never had cause to regret such a course. If one has confidence in the thoroughness of his work, including the security of his wound closure, I cannot understand what he expects to gain by confining the bowels for four, five or six days while the nausea and auto-intoxication continue and the suffering from gas-pains becomes constantly more severe.

It has been my regular plan to begin the administration of calomel in powder form, usually combined with cerium oxalate, twenty-four to thirty-six hours following the operation, giving a half grain of the former and one grain of the latter at a dose every hour until six doses are taken. Four to six hours after the last dose, or sooner if indicated, a purgative enema is given which generally inaugurates active peristalsis; if not, this is repeated at intervals until the desired effect is produced. It is seldom necessary to administer salts or castor oil when this plan is followed, and the combination of calomel and cerium oxalate, as a rule, acts most happily in allaying postoperative nausea. The few days or even hours of discomfort saved the patient without the addition of any appreciable element of risk seem to me not only fully to justify this routine, but also to render it highly desirable from every point of view.

VALUE OF THE METHOD

After stating that for more than three years he had employed the anoci-association technic in every operation, Bloodgood announces his deliberate conclusion as to the value of the method in these convincing words:

> From my observation I am convinced that any operation performed under this method of anesthesia, properly carried out, will result in less shock; the mortality will be lower; the postoperative discomforts and complications will be greatly reduced; the period of disability very much shortened. All this has certainly been accomplished in my own experience, and I think I have convinced my associates, both surgeons and nurses, that the method has great advantages over ether. I am also confident that no operating surgeon will come to the same conclusions until he has faithfully given this method a fair trial over a considerable period of time.

My own convictions on the subject could not have been better expressed. I am sure that the use which I have made of the method has rendered possible the best and most satisfactory work of my surgical experience. In the five months immediately preceding my removal to California, Dr. J. A. Gaines of Nashville, and myself, working together, employed it in about one hundred and twenty-five major operations covering virtually the whole field of surgery. Since coming to Los Angeles last fall I have had the opportunity, for quite obvious reasons, of applying the method in only about thirty cases including cholecystostomy, appendectomy, herniotomy (five), gastro-enterostomy (two), hysterectomy and various operations on the adnexa. In this series, the nitrous oxid has not been uniformly available; but even with ether as the inhalation anesthetic the advantages of this technic have been evident to both the physicians and the nurses who have seen and followed the work. To mention a single example: A gastro-enterostomy for duodenal ulcer was performed on a frail woman of 52. She had no shock, received no opiate or sedative at any time, suffered absolutely no pain and did not even know where the incision had been made until it was shown her on the ninth day. She was sitting up in bed on the fourth day, sitting in a chair on the seventh day and left the hospital on the twelfth day.

Contrasting the mortality rates at Lakeside Hospital before and after the introduction of the anoci technic, Crile shows that for the year 1908, the year preceding its introduction, it was 4.2 per cent.; for the year 1912 operations were performed on 2,672 patients, including all kinds of acute emergency cases, with a mortality rate of 1.9 per cent. In the last thousand operations previous to the time of the preceding report the mortality rate was 0.8 per cent.

Here I submit the question: whatever views one may hold as to the theories on which anoci-association is based, there would seem to be no just ground for doubting or discrediting the practical benefits its application yields. The ethical questions involved I shall not discuss. They are sufficiently apparent and each individual must face and solve them for himself.

In conclusion, I trust I may not appear dogmatic when I say that what a man's judgment approves and his experience confirms, that he knows. If there were no other data than those which my own personal work affords, I should still feel warranted in saying that, in my opinion, anoci-association constitutes the most important contribution to the progress of surgery in the past quarter of a century.

1020 Story Building.

RESULTS FROM THE USE OF LIVING LACTIC ACID BACILLI ON DIPHTHERITIC THROATS IN TWO GROUPS OF CASES

E. V. GOLTZ, M.D.
AND
W. D. BRODIE, M.D.
ST. PAUL

The apparent lack of clinical benefit and subsequent failure to lessen the time of housing in the contagious ward of the City and County Hospital, with the use of living cultures of lactic acid bacilli, led us to abandon further tests in November and December, 1913.

In the fifteen or eighteen cases taken at random in which the lactic acid bacilli were used, there was no appreciable difference in the average time of quarantine from the throats treated in the ordinary manner with mild antiseptic gargles and various local applications.

The recent reports of favorable results have stimulated us to make another and a more detailed attempt, using both the living cultures of lactic acid bacilli and naturally soured milk, in each instance obtaining a control case so far as possible alike.

Mulford's (Bulgarian Type) cultures of living bacilli were used, after testing their activity by obtaining growths on agar-slants. Nose and throat were sprayed two, three and four times daily. No antiseptics were employed and individual atomizers were maintained. The patients receiving the naturally soured milk used this as a gargle and as a nasal douche four and five times daily.

The following six cases with their controls were taken at random from a group of twelve:

Case 1.—*Patient* (No. 66924).—Man, aged 27, admitted March 7, 1914, after being sick two days. On admission, temperature 102.6, pulse 112. Distinct membrane over both tonsils and posterior pharynx, with marked edema of uvula. Antitoxin, total, 20,000 units: 5,000 units before admission, 5,000, 5,000, 5,000 after. Lactic acid suspension spray every day at 10 a. m. and 2, 6 and 10 p. m. Cultures: March 9, 10, 12, 14 and 16, positive; 17, negative; 18, throat positive, nose negative; 20, throat negative; 21, throat and nose negative. Total days in hospital, 14.

Control (Patient 66892).—Boy, aged 11, admitted March 5, 1914, after being sick three days. On admission, temperature 100, pulse 130. Distinct membrane over greatly hypertrophied tonsils and pharynx, and marked edema throughout this membrane, being more extensive than in the foregoing case. Antitoxin, total 25,000 units: 10,000, 10,000, 5,000 all after admission. Locally, Seiler's solution as a gargle four times a day. Cultures: March 10 and 13, positive; 14, throat negative; 15, throat and nose negative. Total days in hospital, 11.

Case 2.—*Patient* (No. 67013).—Nurse, aged 26, admitted March 11, 1914, after being sick two days. On admission, temperature 103, pulse 115. Distinct membrane on right tonsil and pharynx. Antitoxin, total, 13,000 units: 5,000 units before admission, 5,000, 3,000 after. Lactic acid spray, nose and throat, 10 a. m. and 2 and 6 p. m. Cultures: March 14, 16, 21 and 26, positive; 29, negative; 30, throat and nose negative. Total days in hospital, 20.

Control (Patient 66952).—Nurse, aged 23, admitted March 8, 1914, after being sick two days. On admission, temperature 100, pulse 100. Membrane as above. Antitoxin, total, 30,000 units. No sprays. Cultures: March 10, 13 and 15, positive; 16, negative; 17, throat and nose negative. Total days in hospital, 11.

Case 3.—*Patient* (No. 66587).—Nurse, aged 27, admitted Feb. 18, 1914, after being sick two days. On admission, temperature 100, pulse 92. Distinct membrane over entire right hypertrophied tonsil and posterior pharynx. Antitoxin, total, 25,000 units: 8,000, 5,000, 8,000, 4,000. Lactic-acid spray, 10 a. m. and 2 and 6 p. m. Cultures: February 18, 20, 22, 25 and 27, and March 3, 5, 6, 8 and 10, positive; 11, negative; 12, throat and nose negative. Total days at hospital, 23.

Control (Patient 66699).—Nurse, aged 23, admitted Feb. 23, 1914, after being sick two days. On admission, temperature 100, pulse 120. Distinct membrane over both tonsils, most extensive over right, dirty gray in appearance. Antitoxin, total, 10,000 units. Locally, Seiler's solution as a gargle four times a day. Cultures positive up to March 9, except one negative, March 5; following this, March 12, 15, 18, 21, 24, 27 and 30, and April 2, positive; 4, negative; 5, throat and nose negative. Total days at hospital, 42.

Case 4.—*Patient* (No. 66830).—Boy, aged 16, admitted March 1, 1914, after being sick three days. On admission, temperature 98.6, pulse 120. Distinct membrane over both tonsils. Antitoxin, total, 9,000 units: 3,000 before, 3,000, 3,000 after. Lactic-acid spray, nose and throat, three times a day. Spray discontinued March 19. Cultures: March 1, 10, 11, 12, 13. 15. 16 and 18, positive; 20, negative; 21, throat and nose positive; 22, negative; 23, throat negative, nose positive; 24, positive; 27, negative; 28, throat negative, nose positive; 30, negative; 31, throat and nose negative. Total days in hospital, 31.

Control (Patient 66824).—Nurse, aged 24, admitted Feb. 28, 1914, after being sick two days. On admission, temperature 101, pulse 115. Distinct membrane over both tonsils, extensive with more edema. Antitoxin, total, 11,000 units: 3,000, 2,000, 3,000, 3,000. Locally, Seiler's solution as a gargle four times a day. Cultures: February 28 and March 8, positive; 10, negative; 11, throat and nose negative. Total days at hospital, 12.

Case 5.—*Patient* (No. 66497).—Nurse, aged 25, admitted Feb. 13, 1914, after being sick two days. On admission, temperature 102, pulse 110. Dense membrane over both tonsils and pharynx. Antitoxin, total, 5,000 units, single injection. Sour-milk gargle and nasal douche four times a day. Cultures: February 13, 22, 24, 25, 26 and 27, positive; 28, negative; March 29, throat and nose negative. Total days at hospital, 17.

Control (Patient 66553).—Boy, aged 7, admitted Feb. 16, 1914, after being sick two days. On admission, temperature 100, pulse 102. Distinct membrane over both tonsils and pharynx. Antitoxin, total, 5,000 units, single injection. Locally, Seiler's solution as a gargle four times a day. Cultures: February 16, 19 and 22, positive; 24, negative; 25, throat and nose negative. Total days at hospital, 10.

Case 6.—*Patient* (No. 66776).—Nurse, adult woman, admitted Feb. 24, 1914, after being sick one day. On admission, temperature 101, rising to 102.8 at 8 p. m.; 99.8 February 26, and normal, February 28. Distinct membrane over both tonsils. Antitoxin, total, 5,000 units, single injection. Sour-milk gargle and nasal douche four times a day, continued until March 12. Cultures: February 25 and March 5, positive; 6, negative; 8, throat and nose positive; 10, positive; 11, negative; 12, throat and nose negative. Total days at hospital, 15.

Control (Patient 66770).—Man, aged 20, admitted Feb. 25, 1914, after being sick one day. On admission, temperature 101, pulse 96. Distinct membrane over both tonsils. Antitoxin, total, 3,000 units, single injection. Locally, Seiler's solution as a gargle four times a day. Cultures: February 25, positive; March 4, negative; 5, throat and nose negative. Total days at hospital, 9.

CONCLUSIONS

The average quarantine period of the six cases reported in which the lactic acid bacillus was used is twenty days.

The average quarantine period of the six controlled cases treated locally only with Seiler's solution as a gargle is sixteen days.

The average quarantine period of fifty-seven cases admitted to the hospital during January, February and March, 1914, comprising all cases discharged with the required cultures, is twenty-one days.

Lactic acid bacilli in our experience hasten the disappearance of diphtheritic membrane, but will not produce cultures negative to the bacillus.

521 Lowry Building.

Longevity in Indiana.—In the Indianapolis *Star*, May 17, Dr. William B. Clarke gives a long list of names of men and women who surpassed the age of 90, of whom forty-nine reached 100 or more. Of these, one lived to be 120, one was 119, another 115 and still another 114. Six died within a few weeks or months of the century mark. Eight centenarians died in 1912. Fifteen physicians reached ages between 87 and 100, five of whom are still living. One physician, Dr. Pierre Beaugrande, of Mishawaka, reached the century mark, dying April 10, 1914. The next oldest was Dr. W. H. Wishard of Indianapolis, who died Dec. 9, 1913, at the age of 97 and some months.

THE USE OF HERUDIN IN THE TRANSFUSION OF BLOOD[*]

HENRY S. SATTERLEE, M.D.
AND
RANSOM S. HOOKER, M.D.
NEW YORK

The present communication is the last of three reports on experimental work undertaken to develop a more widely useful method of blood transfusion than those already existent. This work was inspired by the recent advances in the study of blood coagulation by W. H. Howell and other investigators of the Baltimore school, which suggested that the practical difficulties of developing a safe and easy transfusion method might be met on a more rational basis in the light of better knowledge; and that the newer laboratory methods of estimating the various factors of coagulation would be a help in forming a more precise judgment as to the efficacy or non-efficacy of measures calculated to prevent harmful changes in transfused blood.

The first part of our experimental work was concerned with influencing the initiative changes of coagulation through preventing or hindering thromboplastin formation by the use of paraffin and a suitable instrumental technic.[1]

The second part of this work resulted in the further development of a practical form of apparatus adapted to paraffin and herudin methods, and especially designed to enable a single operator to perform a transfusion, if necessary, without trained assistance.[2]

The third part of our investigations, concerning herudin, has been in progress along with the work already reported, but we have thought best to reserve the publication of this work until satisfied that the results warranted practical application.

Oxalated, citrated and fluorided plasmas are well known in the physiologic laboratories, and sodium citrate is reported to have been used as an anticoagulant for small quantities of transfused blood. Oxalate and citrate solutions act by fixing the calcium of the blood, which is a necessary factor in spontaneous coagulation. This decalcification is, of course, a change produced by a chemical reaction in the blood, and is theoretically, at least, undesirable. The use of herudin as an anticoagulant is not open to this objection.

Herudin is the active principle of a secretion derived from the buccal glands of the pond-leech, *Sanguesuga medicinalis,* and has been classed by Franz as a secondary albumose. Its physiologic properties are variously regarded by different investigators. Morawitz believes that it acts by neutralizing thrombin and prothrombin (thrombogen). Shittenhelm and Bodong believe that it neutralizes neither of these factors but reacts with some, as yet unknown substance, which is derived from the plasma. Mellanby concludes, from what appears to be substantial experimental evidence, that herudin contains an antibody for prothrombin and also a very energetic antibody for thromboplastin (kinase).

It may be concluded fairly from the available evidence that herudin has a decided effect on the prothrombin-antithrombin balance and that it has a neutralizing action on thromboplastin. This action is best illustrated diagrammatically.

The scheme of representation is based on Howell's theory of the mechanism [illegible] nd provides, we believe, an adequate [illegible] phenomena which have been observed. According to this theory the potential factors of coagulation may be expressed as shown in the diagram of the circulating blood (Fig. 1 *A*). The fibrinogen and calcium occupy a neutral position but have a potential affinity for prothrombin. The antithrombin and prothrombin have an affinity for each other and are loosely combined. This combination constitutes a balance, the so-called antithrombin-prothrombin balance, which, in normal circulating blood, is not quite equal, because there is a slight preponderance of the antithrombin. If anything happens to upset this balance, so that the antithrombin side is weakened, then some of the prothrombin is released, and, in the presence of free calcium, becomes thrombin; and this thrombin reacts with fibrinogen to form a clot.

Figure 1.

This action is seen in Figure 1 *B*. Here the coagulative process is initiated by the advent of another element, thromboplastin, which, having a very marked affinity for antithrombin, diverts it from its prothrombin attachment, and clotting ensues in the manner indicated.

In Figure 2 it will be seen that the action of herudin is to intervene and bind the thromboplastin, thus preventing the deviation of antithrombin from its prothrombin attachment.

There is considerable literature on the experimental use of herudin and there are some reports on its therapeutic use by intravenous injection for eclampsia, but no mention of its use as an anticoagulant for transfusing human blood.

From our experimental work it has become evident that herudin affords a convenient alternative for the paraffin method of transfusion under most circumstances. The amount of herudin necessary, with our apparatus, is so small that its use may not be contraindicated even in those pathologic conditions in which there is already an excess of antithrombin or a deficiency of prothrombin in the circulating blood of the recipient.

Sievert has published a series of experiments which indicate that intravenous injections of herudin in rabbits are toxic in very large doses, that is from 25 to 50 mg. per kilogram of body-weight, the toxicity showing itself by changes in respiration and temperature, apathy, somnolence and albuminuria. Sievert states that the higher dosage, if quickly repeated, may result fatally, and that necropsy reveals hyperemia and petechial hemorrhages of the kidney and spleen but no other lesions. Other observers have found comparatively little or no ill effect from the intravenous use of large doses of herudin. Kaposi has given 40 mg. of herudin in normal salt solution by intravenous injection to a 2-kg. rabbit without harming the animal, and designates this proportion, 20 mg. per kilogram of body-weight, as the normal dose for experimental work. Rimann and Wolf, using this dosage, particularly state that no disturbance of health was noted as a result. Cowie has given thirty-five intravenous injections of herudin to a rabbit in doses increasing from 10 mg. to 22 mg. in twenty-six days, and maintained the last-mentioned dosage until the final injection, the total period of treatment covering fifty-four days. At the end of this time the animal had gained in weight and was in every respect perfectly well. Bodong has given from 23 to 73.25 mg. per kilogram of body-weight to rabbits, and states that it has no influence on the circulation or the respiration and is in no other way harmful to the animal. Von Hertzen and Ohman have confirmed Bodong's observation in a series of twelve experiments and concluded that herudin has no disturbing effect on the heart and blood-vessels. Abel, Rowntree and Turner have used very large quantities of herudin in "vividiffusion" experiments on dogs without apparently impairing the normal physiologic condition of the surviving animals. Dienst reports that he has given 200 mg. in 50 c.c. of salt solution by intravenous injection to a patient with very severe eclampsia, with most excellent results; and Engelmann has reported fourteen cases of eclampsia treated in this way with doses of from 200 to 300 mg.

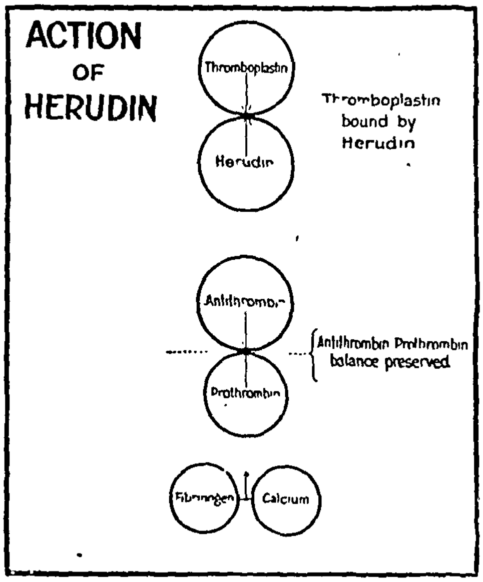

Figure 2.

Rimann and Wolf, in a series of eight experiments on the circulating blood of rabbits, have found that 20 mg. of herudin per hundred gm. of blood (normal dosis of Kaposi) renders the blood uncoagulable for four and a half hours, and that 10 mg. per hundred gm. of blood results in a shortening of the period of incoagulability to from one and a half to one and three-fourths hours. In these experiments the herudin was injected intravenously and the amount of circulating blood was calculated as one-tenth of the body-weight. The evidence of a coagulative tendency in the circulating blood following the injection was obtained by introducing a thread of catgut within the blood-current, according to the method of Trendelenburg. This catgut was withdrawn at varying intervals and the earliest appearance of fibrin formation was noted.

EXPERIMENTAL BASIS OF THE METHOD

Our first aim in experimenting with herudin was to determine the minimal amount of this substance which, when used in conjunction with the best available technic, would serve to prevent coagulative changes for a sufficient length of time to insure a safe transfer of blood from donor to recipient. The first experiment of this series was designed to show the amount of herudin necessary to defer coagulation from one-half to three-quarters of an hour when mixed with blood which was withdrawn directly from the vein so that there was the least possible chance of contamination with traumatized tissue. In this experiment no paraffin was employed, the blood being taken from a vein in 1-c.c. glass pipets and transferred immediately to six glass tubes containing varying amounts of herudin in 0.9 per cent. sodium chlorid solution.

From this experiment it was estimated that about *3.5 mg. of herudin to 100 c.c. of blood would be* requisite for purposes of transfusion without the aid of paraffin, provided good technic was employed in obtaining the blood free from admixture of tissue juices.

This, in actual trial with our regular apparatus, was found to be the case; but the time of onset of coagulation varied within fairly wide limits — from seven to fifteen minutes.

When a paraffin coating was applied to the tip and the neck of our transfusion pipet it was found that the amount of herudin could be reduced by half, or to 1.5 to 1.8 mg. per hundred c.c. of blood; and that under these conditions there was also a twofold lengthening of the time of onset of coagulation. This meant a fourfold increase of efficiency of the herudin in the presence of a paraffin lining of the tip of the transfusion pipet.

As compared with a 30-c.c. piston-syringe with cannula 1 mm. in diameter and 30 mm. in length, 4.0 mg. per hundred c.c. of blood gave a clotting-time of ten minutes and thirty seconds for the syringe method, whereas 1.5 mg. per hundred c.c. of blood gave a clotting-time of thirty minutes for the paraffin-sealed pipet; and this, by a simple computation, shows a relative efficiency of approximately 1:8 in favor of the pipet.

To demonstrate the effect of herudin as applied to our method of transfusion, we have appended a table including all of our experimental and clinical transfusions with herudin in which no special factors were introduced (as varying pressures in delivery of blood, etc.), which would influence the onset of coagulation in the blood which was reserved in the pipet for observation. Experimental Transfusions 5 and 6, in which no paraffin was used as a lining for the tip of the pipet, are included in this table for the special purpose of comparison with our preferred method, in which the tip of the pipet is paraffin-sealed and lined.

EXPERIMENTAL AND CLINICAL TRANSFUSION WITH HERUDIN

Exp. Transfusion 19	220	3	1/500	30	38

* In these experiments the tip of the pipet was not lined with paraffin.
† Not observed.
‡ No clot at 38.

PRACTICAL APPLICATION OF THE METHOD

In making use of herudin for transfusion we have employed our regular pipets and cannulas, but we have dispensed with the paraffin coating of the cylinders. We have prepared the pipets by introducing from 3 to 5 c.c. of a 1:500 solution of herudin in salt solution, flowing this liquid very thoroughly over the interior of the cylinder and draining away the excess through the tip of the pipet just previous to use. From 1.5 to 2 c.c. of this solution, or approximately 3 mg. of herudin, are retained by adherence to the walls of the pipet, and for more than twenty minutes this is sufficient to prevent 220 c.c. of blood, drawn into the pipet, from clotting.

With the exceptions already noted, the operation with herudin is conducted in precisely the same way as with the paraffin-coated apparatus. The preparation of the pipets is the same, except that the first coating of the cylinders with paraffin is omitted. A partial coating with paraffin, however, is advisable. This coating should be done by aspirating the sterile, melted paraffin mixture just within the neck of the cylinder and expelling it again. This use of paraffin, from the tip to the neck, is primarily to insure an airtight junction of the pipet tip with the metal bushing, and of the latter with the neck of the cylinder, but it also has a demonstrable effect in lessening thromboplastin formation during the aspiration of blood, and permits the employment of a minimal quantity of herudin. The herudin method may be employed without any paraffin whatever by using a 1:300 solution of herudin for coating and with care that the interior of the pipet tip is perfectly smooth and brightly polished, and that all connections are tight against air-leakage; but these contingencies are so surely and easily provided for by aspirating a little sterile paraffin just above the neck of the pipet, that the latter method is to be preferred. Any small receptacle with a cover and alcohol heating device will answer the purpose for sterilizing and holding the paraffin. The hardened paraffin may thus be carried with the apparatus, and the sealing process may be done at the time of operation, allowing ten or fifteen minutes for the pipet to cool, before coating with herudin solution.

It would, no doubt, be possible to obtain a more accurate estimate of the coagulation factors in transfused blood, and also of the inhibiting effect of herudin, by quantitative determinations of thrombin and of thromboplastin in specimens of such blood under varying conditions. We believe, however, that the simple observation of onset of coagulation together with the amounts of blood and of herudin, as recorded in the table, justify our conclusions. We hope at some future time to follow our present work with a more complete investigation of the subject with the aid of more precise laboratory methods.

ARTHROPLASTY FOR INTRA-ARTICULAR BONY AND FIBROUS ANKYLOSIS OF TEMPOROMANDIBULAR ARTICULATION

REPORT OF NINE CASES *

JOHN B. MURPHY, A.M., M.D., LL.D., F.R.C.S. (Eng.)
CHICAGO

Arthroplasty, or the technic for the formation of new joints, may be divided into seven different stages in its evolution, and each stage has been initiated or created by the work of a single individual and then his succeeding school. These stages are:

1. The formation of fibrous or flail joints, as of the shoulder and elbow (Langenbeck, Ollier, Julius Wolff and others). These were desired sequences following resections for diseased joints, as tuberculosis, syphilis, pus infections, etc.
2. The restoration of mobility in a bony ankylosed joint by the interposition of muscle and fibrous tissue between the separated ends at the ankylosed joint, as in the mandible (Helferich, 1893, who was the father of this method).
3. Pseudo-arthrosis developing after osteotomies in the neighborhood of joints (Lorenz), as in hip ankylosis.
4. The transplantation of pedicled flaps of fascia and fat and capsule, with the production of a movable, sliding joint and a hygroma (Murphy, 1902), in the mandible, hip, knee, elbow, shoulder and wrist.
5. The homotransplantation of the articular ends and surfaces of bone (Lexer, 1906), particularly in the knee.
6. The transplantation of free fat and fascia (Lexer).
7. The interposition of foreign material to make the joint, from Péan's metallic joint down to Kraske, Baumgarten, Roser and Baer's heterovisceral implantations.

---

* Read before the meeting of the American Surgical Association, New York, April 9-11, 1914.

The fourth stage, or the transplantation of pedicled flaps of fascia with fat and capsule, is the one now in vogue. It is to be hoped that the free fascia and fat transplantation of Lexer will with future experience sustain the good results which its originator predicts for it, as there are many cases in which a pedicled fat and fascia flap is not available, on account of the anatomic conditions and particularly the pathologic sequences preceding or associated with the development of the ankylosis.

Heteroplasties and the insertion of foreign material are doomed to disappear from this field of work, as foreign absorbable material, if aseptic, must eventually be supplanted by connective tissue; and while a flexible joint may be present, a movable sliding joint cannot result from such interposition. Non-absorbable metal materials can be serviceable only under a few very favorable conditions.

So much for the general subject of new joint formation or arthroplasty. Concerning arthroplasty of the jaw, I would say that ankyloses of the jaw may be divided into (1) the intra-articular fibrous and osseous and (2) the extra-articular cicatricial varieties. The latter may also be termed the interalveolar or cheek cicatricial fixation, the result of sloughing in the mouth and infections of the subzygomatic zone.

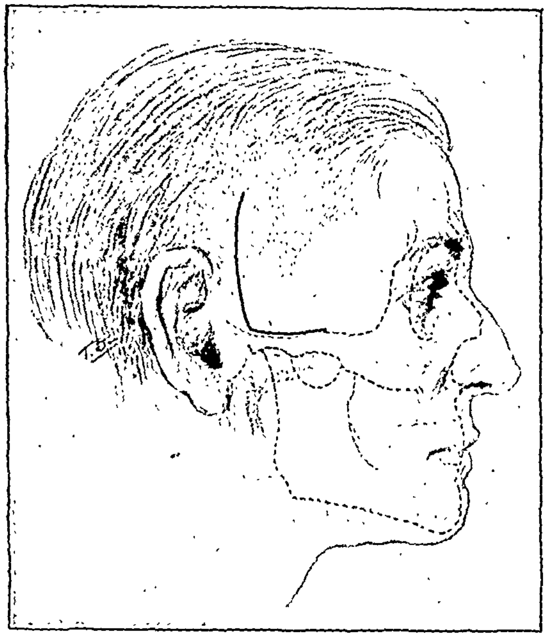

Fig. 1.—The line of incision and the bony outlines at the point of ankylosis.

ROUTES OF INVASION OF THE JOINT

The most common type of ankylosis is the bony. It may be due to:

1. An extension of a suppuration from the middle ear (Case 1).
2. A mandibular osteitis extending to the glenoid cavity.
3. A metastasis from foci of infection elsewhere in the body (Case 9), or it may be part of a general metastatic arthritis (Case 7).
4. It may be the result of a transmitted trauma from the chin (Case 4).

The ankylosis may involve the head of the mandible only, or it may extend across to the coronoid process, so that the lower maxilla is firmly welded to the temporal bone and the base of the zygoma by the new bone formation. It is common to have it include the anterior root of the zygoma.

In most cases the cause of the ankylosis is a middle-ear suppuration. If one follows the anatomic course of these suppurations, it is obvious how the mandibular articulation becomes involved. Infections of the middle ear penetrate in five different directions:

1. The infection may pass backward into the mastoid.
2. It may pass through the posterior wall of the petrous bone into the posterior cerebral fossa.
3. It may penetrate the attic of the ear, form an abscess within the middle cerebral fossa and rupture externally just above the tip of the ear.
4. The abscess may burrow forward and rupture into the glenoid cavity or pass over the base of the zygomatic process into the mandibular articulation.
5. The abscess may burrow forward into the subzygomatic temporal muscle zone and produce a great phlegmonous myositis with subsequent cicatricial contraction.

In the case of para-articular fixation, due to the formation of cicatrices, the condition is usually caused by a sloughing of the mucous lining of the cheek, such as follows typhoid fever, scarlet fever or measles (noma), infections of the alveolar processes, subzygomatic infection from penetrations through the mouth or cheek, from infections of the scalp or cranium by producing destruction of the fascia and temporal muscle which may contract in the process of repair and so cicatrize as to fix the jaw absolutely on that side.[1]

DIFFERENTIAL DIAGNOSIS

The differential diagnosis as to which side is involved is often extremely difficult. When the ankylosis is bony, there is complete fixation of the jaw. When the ankylosis is fibrous, there is some motion in the jaw, depending on the degree of joint involvement (Case 3). In the para-articular ankyloses, there is always some motion in the jaw. In the intra-articular ankyloses, there is sometimes a little lateral motion on the unaffected side, from 1/60 to 1/100 inch on forced effort at opening the mouth, a point in diagnosis which is well worth remembering.

I have learned by clinical observation and experience that a diagnosis of the side involved can be made accurately (when only one side is affected and if the condition occurred early in life) by noting the deviation and contrast formation of the two sides of the face. The face on the side of the ankylosis is full and round and apparently normal in appearance. On the opposite or unaffected side it is flattened and deformed. The chin is always more or less retracted and deviates toward the ankylosed side. If the ankylosis occurs after the patient has attained full growth, this deviation is only slight in degree; but if it occurs in infants or children, the deviation and retraction are marked, increasing in degree as the patient grows older. The earlier the ankylosis has occurred in life, the greater the deformity of the face (Case 1). The fixation of the joint interferes with the proper development of the jaw. The epiphysis of the condyle is the means through which the ramus grows in length.

---

[1] Murphy, John B.: Use of Palate Mucous Membrane Flaps in Ankylosis of the Jaw Due to Cicatricial Formations in the Cheek, The Journal A. M. A., July 26, 1913, p. 245.

This growth is arrested by the ossification across the epiphyseal line before the normal time for ossification, which is the fifteenth year. All of the other five centers of ossification are united by bony formation before birth. The absence of use of the jaw undoubtedly is a contributing factor to its aplastic condition. When the ankylosis is a recent one there is not much deformity (Case 4).

PHYSICAL FINDINGS

The physical findings in these cases are the following:

1. There is flattening of the jaw on the unaffected side, most pronounced near the tip of the chin.
2. When the patient attempts to open his mouth, the teeth move from 1/60 to 1/100 inch downward and deviate a little in the direction of the ankylosed side, because of a slight sliding forward of the mandibular articulation on the unaffected side as the muscles of the neck are put on tension in the effort made to open the mouth.
3. A sliding motion on the unaffected side can be felt by the palpating fingers, and the muscular activity on that side is very much greater on attempted opening of the mouth than on the ankylosed side.
4. The muscles on the ankylosed side are more atrophied than those on the unaffected side.

In only one case (Case 1) of this series of nine intra-articular ankyloses of the temporomandibular articulation was there failure to diagnose the side affected, and in that case I was entirely misled by the history given us. All the data, including the mother's information, pointed to the left side as the one involved in the original lesion (a middle-ear abscess which had been opened and drained), when, as a matter of fact, the ankylosis was on the right side, and therefore the history could not have been correct. That case taught me to base the diagnosis on the points mentioned above rather than on the history.

TECHNIC OF OPERATION

In all of these cases of ankylosis of the jaw of the intra-articular type I have performed a typical and uniform arthroplasty, and the results which we have obtained have justified me in advocating this exact technic for these cases. The technic of this operation is not difficult, but it must be exact in its details in order to secure good results. I have employed the pedicled flap as the interposing material. It consists of fat and the aponeurosis of the temporal muscle, and sometimes includes a few muscle fibers.

In my earlier operations I fixed the tip of the flap to the connective tissue and internal portion of the capsule. Later I abandoned this procedure, and now I fix the flap at the basal angles only; by this method there is not that danger of injuring the internal maxillary artery, an accident which I encountered in one of my early cases. This flap is of the same shape and material as that used in my operations in 1902, but at that time I brought the flap under the zygoma down into the joint, while now I turn it over the zygoma into the joint.

At first I exposed the joint by a perpendicular incision just in front of the ear, extending from 1½ inches above the zygoma in the hair-line downward to the lower border of the zygoma. Later, I modified this incision, curving it slightly forward on the temple at its upper extremity. And then I adopted an L-shaped incision (the one I make now); the perpendicular portion comes down to the upper border of the zygoma and then extends forward along its upper margin for a half to three-quarters of an inch, making the longitudinal portion (Fig. 1). That is a very satisfactory incision, one which leaves a very slight scar, most of it being hidden in the hair. It gives better access to the joint than does the perpendicular incision, because in some of my cases of bony ankylosis, the ankylosis extended forward on the zygoma from the glenoid to the *coronoid process*. The *perpendicular incision* is made for the purpose of securing the fat and fascia of the temporal muscle.

I have divided the ankylosis by means of chisels, Gigli saw or with an olive-tipped dental burr driven by an electric motor. The latter is much more rapid, but, on the whole, is not so satisfactory, I believe, as the chisel. It is needless to point out that the greatest caution is required in the use of the chisel, or the burr for that matter, because of the close proximity of the brain, which is separated from the head of the mandible by a very thin transparent plate of bone only.

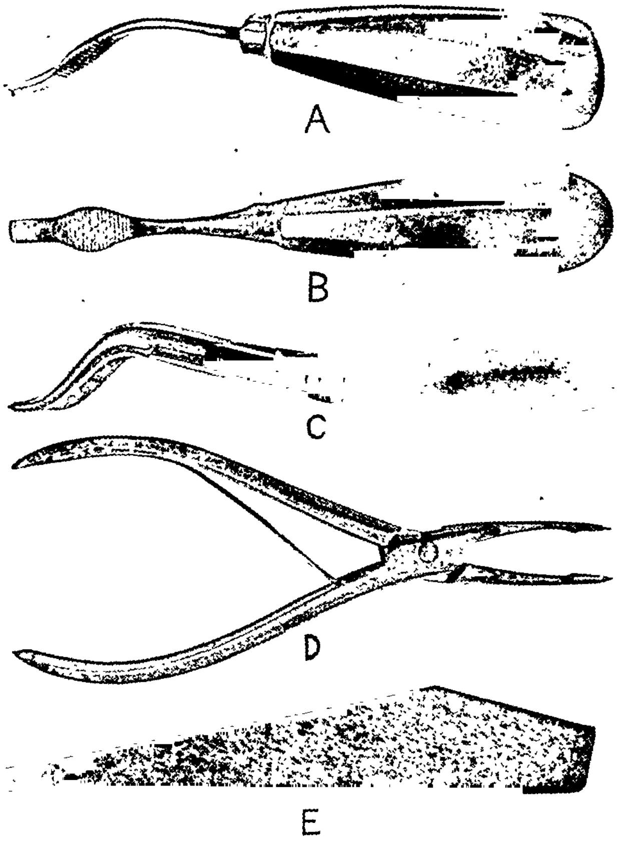

Fig. 2.—*A, B,* Dr. Murphy's periosteotome, side and back view (somewhat reduced); *C, D,* bone-cutting forceps or nippers, side and front view (somewhat reduced); *E,* the interdental block designed by Dr. Murphy to maintain the desired spread of the jaws. It is made of wood and since it is wedge-shaped, the degree of opening can easily be regulated by withdrawing or pushing in the block.

DETAILS OF THE OPERATION

After the incision has been made, as described above, the edges of the wound are retracted, the lower lip being displaced downward over the lower border of the zygoma, in order to give a good exposure of the joint. Then the tissues are separated with a *special* curved periosteotome (Fig. 2, *A* and *B*) all around the anterior surface of the line of union and further separated with a similar instrument around the posterior surface. When the bone is laid bare, the two instruments are passed behind the neck of the bone, one from each side, so that when they are in place they completely encircle the neck of the mandible behind close to the head, holding the soft parts retracted during the excision of the bone, so that the articulation is fully exposed (Fig. 3). The insertion of these instruments and their retention in position during the excision of the bone form the key to the success and safety of the operation. Injury to the internal maxillary artery, which closely hugs the neck of the mandible, is thus avoided. These periosteotomes also act as retractors, keeping the field open for inspection during all of the work. The chisel or burr then divides the bone on the level of the tubercle, without endeavoring to remove the articular surface of the head of the bone, as there is danger of penetrating the base of the skull when an effort is made to excavate all of the head. If bony ankylosis is present, ⅓ inch of the neck is excised, so that one can put the tip of the finger between the divided fragments across the space over the inner margin of the neck at the base of the zygoma. This must be done carefully, and ample bone must be removed, so as to admit of the insertion of the interposing flap of fat and fascia. The periosteum should be left attached to the bone that is removed. The deeper fragments of the bone can be taken out with a small rongeur (Fig. 2, *C* and *D*). If one desires, as soon as the periosteotomes have been passed behind the neck of the bone, a small and full-curved aneurysm needle may be used to carry a silk thread around the neck of the mandible. This thread acts as the carrier for the Gigli saw (Fig. 4), which is used to divide the bone; this method is rapid and effective. The difficulty of inserting the saw is slight, but the acute angulation of the instrument, which necessarily occurs, occasionally causes it to break, giving one some inconvenience in replacing it. On the whole, I do not see that it is handled as easily as the chisel. As soon as the bone is completely divided, the mouth can be opened readily by the anesthetist (Fig. 5).

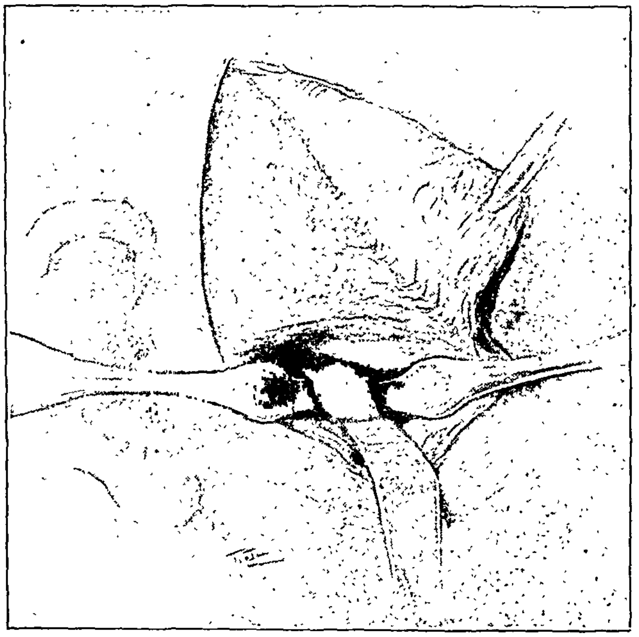

Fig. 3.—The curved periosteotomes encircling the condyle and neck of the mandible.

The interposing fat and fascia flap should now be prepared. The perpendicular incision is elongated up on the temple, say for a distance of 1½ inches. Then a U-shaped flap of fat and fascia is elevated from over the temporal muscle, about ¾ inch wide and 1½ inches long, leaving the base attached to the upper margin of the zygoma. This flap is freed from above downward, folded downward over the zygoma and packed into the bony gap previously described, from which a portion of the neck of the bone has been removed. The flap is packed into the cavity, and at its anterior and posterior basal angles it is securely tacked, with a few catgut sutures, to the fascia and periosteum, so as to retain it in position (Figs. 6 and 7). Then the skin wound is accurately closed with horsehair, dusted with bismuth subiodid and sealed with collodion gauze. No other dressing needs to be applied. The scar is scarcely perceptible and is almost entirely within the hair-line.

No special effort should be made at this time to spread the jaws, as it is important that the lower jaw should remain steadied on the well side in order that the wooden block (Fig. 2, *E*) inserted on diseased side may maintain the wide separation of the molar teeth, until the interposing flap has healed in. This block also prevents compression and necrosis of the flap.

Summarizing the whole technic, the steps of the operation are as follows: (1) the L-shaped incision; (2) division of the ankylosis and removal of a segment of the mandibular neck; (3) raising the flap of temporal fascia and fat; (4) interposing the flap and fixing it in place; (5) closure of the wound.

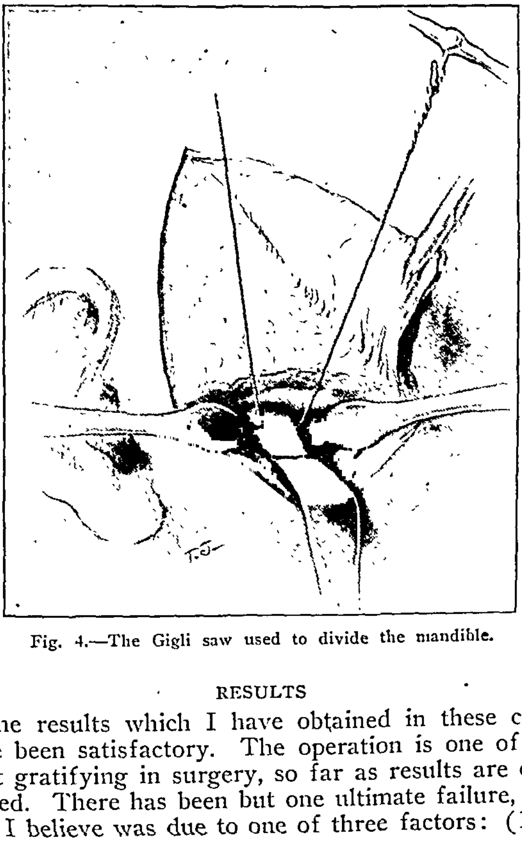

Fig. 4.—The Gigli saw used to divide the mandible.

RESULTS

The results which I have obtained in these cases have been satisfactory. The operation is one of the most gratifying in surgery, so far as results are concerned. There has been but one ultimate failure, and that I believe was due to one of three factors: (1) I did not remove the periosteum with the bone; (2) there possibly was absorption of the interposing flap with ossification of the new-formed connective tissue, as occurs in detached trochanteric fascial flaps in arthroplasties on the knee and other joints, and (3) the parents did not carry out the instructions as to maintaining the wooden plug in position after the patient left the hospital.

In this case (Case 4), seen last nine months after the operation, there was limitation of motion, but not a bony ankylosis. The boy's parents did not attend to the blocking of the teeth since his discharge from the hospital two weeks after the operation, as they were instructed to do. He had good motion immediately after the operation. The immediate successes have been complete.

I have had nine cases of intra-articular ankylosis and two of extra-articular fibrous fixation. In the last-mentioned two cases, I employed the method which I believe is original with me. It consisted in the utilization of mucous membrane pedicled flaps taken from the hard and soft palate as an interposing medium between the divided cicatricial connective-tissue masses for the purposes of preventing a recurrence of the fixation.

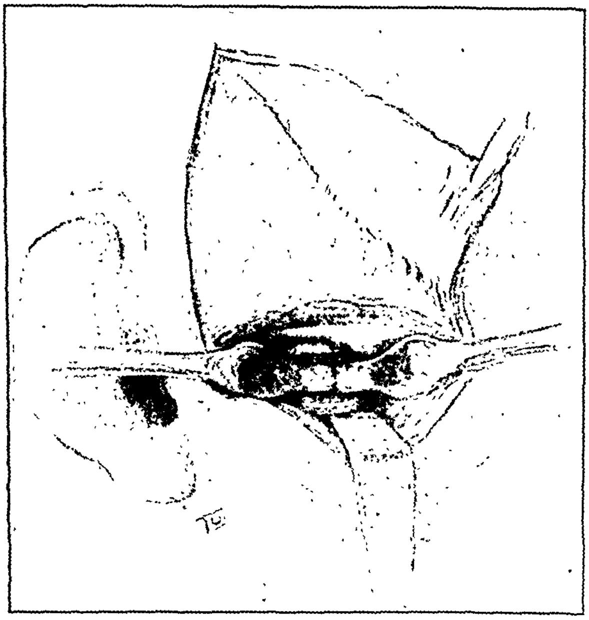

Fig. 5.—The gap left after the exsection, with the curved periosteotomes still *in situ.*

REPORTS OF CASES

CASE 1.—*Ankylosis of Right Temporomaxillary Articulation.*—F. D., boy, aged 15, was admitted to Mercy Hospital, Sept. 3, 1912, on account of absolute fixation and deformity of the lower jaw. The history given by his family was as follows:

> When he was 6 months old a swelling developed rather suddenly in front of the tragus of the "left" ear. A few days afterward pus discharged from the ear through the external canal for four or five days and then the swelling disappeared. There was no swelling over the mastoid then nor has there been since. In fact, there has been no further trouble in that ear. His parents stated that he had no throat or skin trouble and that there was no noticeable deformity of the jaw then. Not until twelve months after the ear trouble did they note that his jaw was fixed. Since then he has been unable to open his mouth.

Examination.—The lower jaw is deformed. The normal angle is absent. The chin is narrow, pointed, recedes and is situated to the right of the median line. The molar teeth articulate normally, but the upper front teeth project beyond the lower about half an inch. The skin for a thumb's breadth to the left of the symphysis menti is contracted. This contraction extends into the tissues of the neck. The lower jaw is pressed firmly against the upper, so that the patient has no motion in any direction. There are no enlarged lymph-nodes perceptible in the neck. There is no discharge from either ear now and no signs of a recent or old mastoid trouble. There is also a marked retraction of the jaw, with a considerable flattening of the left side of the face (Figs. 8 and 9).

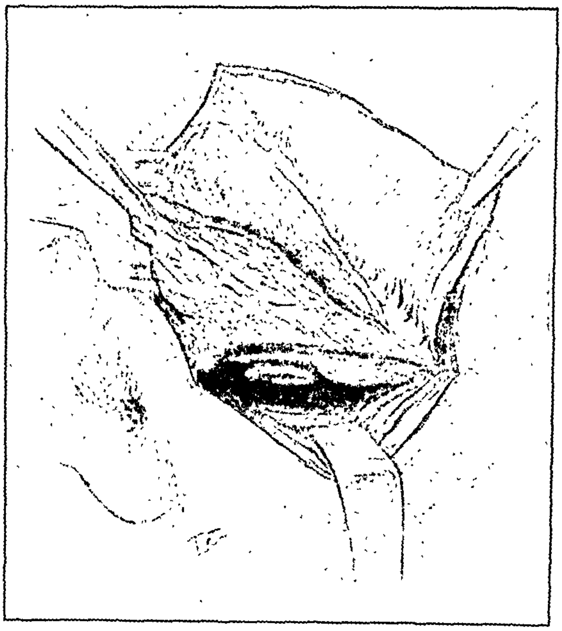

Fig. 6.—The temporal fascia and fat flap freed and prepared for insertion.

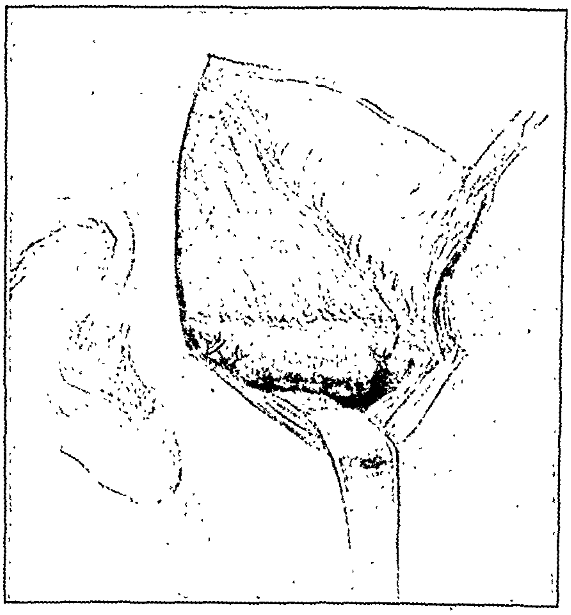

Fig. 7.—The temporal fascia and fat flap secured in its interposing position by sutures.

Operation.—As all the data which could be obtained in this case pointed to the left side as the seat of the trouble, it was concluded to operate on that side. Sept. 7, 1912, a 2-inch perpendicular incision was made, extending along the front of the ear on the jaw, commencing an inch and a half above the zygoma and extending down to its lower margin. Most of the incision was in the hair-line, so that very little of the scar would be visible later. The tissues were divided close to the ear, retracted forward on the cheek and down below the zygoma out of the field of operation. The joint was exposed at once. There was no intra-articular ankylosis, but a capsular contraction was present, the result of the long fixation of the joint. The attachment of the temporal muscle to the mandible was freed, but the jaw remained fixed.' A second incision was made just beneath the angle of the jaw parallel with the ramus, and through this the masseter was freed from its attachment, as well as the internal pterygoid. Still there was not a particle more motion in the jaw than before.

The roentgenograms in this case were very indefinite, as they usually are in these cases, and no assistance was received from them.

This being one of the early cases of ankylosis of the jaw, I had not yet learned to recognize from the facial deformity which side was involved. Later, I learned that the full side of the face was the one to attack and not the flattened side. The failure to get the jaw to drop after the division of these three muscles led me to the conclusion that a mistake might have been made by the parents and friends of the boy in giving us the history, and that it was the right and not the left side which had been involved primarily when he had his ear trouble. Therefore I immediately exposed the right mandibular articulation.

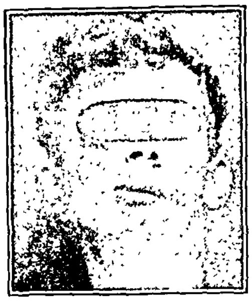

Fig. 8 (Case 1).—Marked flattening of left side of face and fulness of right side. Considerable deviation of chin to the right of the median line.

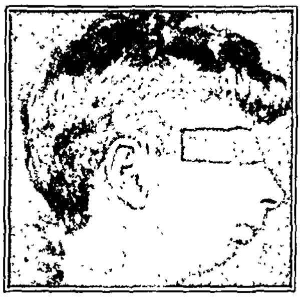

Fig. 9 (Case 1).—Great retraction of the skin; in fact, there is hardly any chin. This is characteristic in these cases, when the condition occurs early in life.

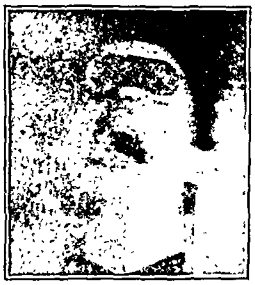

Fig. 10 (Case 1).—Six months after operation; patient's mouth wide open.

An incision similar to that which was made on the left side was made in front of the right ear. The zygomatic attachments were divided at the ear and retracted onto the face out of the field, and when the joint was exposed, I found a bony ankylosis of the articulation, extending forward to the tubercle on the zygoma. It was one solid bony mass. This showed conclusively that the error had been made by the boy's parents in stating that it was the left side that had been involved in the middle-ear infection. My findings showed that it must have been the right side. This ankylosis was divided about a line below the anatomic articulation with a carpenter's narrow straight chisel, a portion of the condyle of the mandible was removed and the jaw immediately dropped down. There was free motion. A flap was then raised from the temporal muscle, consisting of fascia and fat. The tip of the flap was turned down into the joint and interposed between the temporal bone and the mandibular neck, so as to prevent the recurrence of the ankylosis. The flap was tacked in place at its tip to the internal capsule on the neck of the mandible with a few chromicized catgut sutures. The zygomatic attachments were replaced in their normal position and fixed. The deeper portion of the wound was closed with catgut and the skin incision with horsehair. The wound on the left side of the face was also closed with horsehair. Collodion gauze dressings were applied.

Result.—On the morning of the next day the patient was able to open his mouth voluntarily far enough to introduce two fingers. Further progress was uneventful. He had motion in his jaw, free and voluntary, and no pain. The stitches were removed on the sixteenth day. There was primary wound healing. The range of motion was increased rapidly by placing a wooden wedge between the teeth. Word was received from the boy six months later that he could hold an apple in his mouth (Fig. 10).

This case is interesting because of the fact that ossification occurs in certain white fibrous structures in the embryo, and these structures have a tendency to ossify in postnatal life, if subjected to infection or irritation.

The result in this case was encouraging in every way, and in none of the subsequent cases did I fail to make a correct diagnosis as to which side was involved.

Case 2.—*Ankylosis of Right Temporomandibular Articulation.*—A. D. C., man, aged 24, was admitted to Mercy Hospital, April 9, 1913, on account of ankylosis in the lower jaw. Eighteen years ago he was kicked by a horse on the left side of the jaw just posterior to the mental angle, and sustained a compound fracture at this point. The wound suppurated and discharged pus for about two months, when a sequestrum of bone or a tooth — he does not know which — was extruded from the wound, which then healed. Immediately after the accident the patient also had a discharge from the right ear which persisted for some time, he does not know just how long. He never had any pain in the ear before the discharge appeared or afterward. The fixation of his jaw was consequent to this ear discharge. In order that he might feed himself the upper right canine and bicuspid were removed (Fig. 11). The personal and family histories were otherwise negative.

Examination.—The lower jaw was fixed and immovable. The right side of the face was full and round (Fig. 12). The left side was slightly flattened from the angle of the jaw to the chin. The latter deviated to the right of the median line; the patient also had a considerable retraction of the chin. The roentgenogram (Fig. 13) showed a complete obliteration of the right temporomandibular articulation. There was a bony ankylosis extending forward on the tubercle of the zygoma.

Operation.—April 17, 1913, the articulation was exposed by a 2-inch curvilinear incision beginning at the lower level of the tubercle of the zygoma half an inch in front of and on a line with the external auditory canal and extending upward into the hair in a curved direction. By retracting the wound edges and elevating the periosteum with a periosteotome, the site of the articulation was exposed. All anatomic landmarks were lost. An elevation that felt like the head of the mandible was visible and there was some fibrous tissue resembling the capsule of the articulation. There was no motion in the joint. The periosteum was very carefully removed from the head of the bone, and the ankylosis was divided with a narrow straight chisel. It extended forward to the tubercle, binding the mandible firmly to the zygoma. The head of the mandible was then removed with a bone-cutting forceps, leaving a space half an inch in width in which was placed the flap of fat and fascia deflected from the temporal muscle. The temporal flap measured 2 inches in length and an inch in width. It was raised from the temporal muscle and dropped down over the zygoma into the glenoid fossa, so as to cover the raw bony surfaces completely. The tip of the flap was fastened to the capsule on the internal surface of the mandible by means of a few tacking catgut sutures. The basal angles were likewise fixed. The skin wound was closed in the usual manner.

The jaw moved quite freely after the operation. It was found that the opposite articulation was quite stiff, owing to a fibrous fixation, but nothing was done at this time to overcome it, as I preferred to keep it set until the wound healed and the vitality of the flap was assured. A week later the patient was again anesthetized and this fibrous fixation was overcome by forcibly prying open the mouth, care being taken not to injure the teeth or to fracture any of the bones. Success attended this effort.

Result.—The day following the operation, the patient had free voluntary motion in the jaw, which increased rapidly in range. The stitches were removed on the tenth day. There was primary wound healing. The mouth could be opened for 1 inch. When the patient left the hospital on the twenty-second day he could open his mouth for a distance of an inch and a half. A report received nine months after the operation states that the result is a most satisfactory one (Fig. 14).

There are several interesting points in connection with this case which bear emphasis. This man was kicked by a horse on the left side of his face and had a discharge from the right ear. He had no scar on the right side of the face. He evidently had a metastatic infection in the right temporomandibular articulation, and the abscess opened into the ear. He did not have an extension of the infection throughout the entire length of the chin, such as one encounters in mouth infections, typhoid infections or phosphorus necrosis, in which the whole lower jaw from symphysis up to the mandibular articulation may be involved, so that the head of the bone becomes necrotic and is exfoliated. In those cases the whole jaw may be removed as a sequestrum. There was no evidence that this patient had any such infection. We do know, however, that he had an injury of the left side of the jaw and that he had an infection in the right temporomandibular articulation. That is the condition which produced his ankylosis.

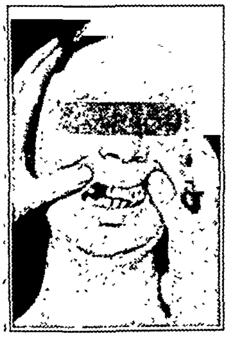

Fig. 11 (Case 2).—The lips are retracted to show the fixation of the jaw and the gap in the denture through which the patient fed himself for eighteen years.

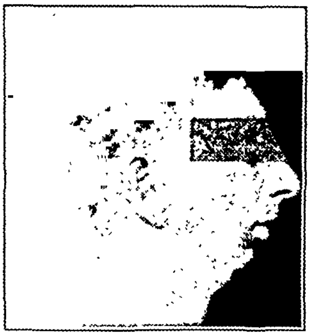

Fig. 12 (Case 2).—Lateral view, showing the retraction of the chin. It is evident that that side of the face, the right, is not flattened. It was the right articulation that was ankylosed.

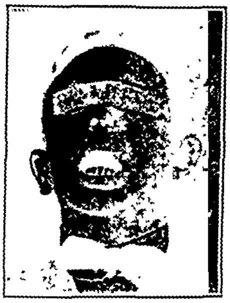

Fig. 14 (Case 2). — Eleven months after operation; patient able to open the mouth practically to the normal degree.

CASE 3.—*Fibrous Ankylosis of Left Temporomandibular Articulation.*—W. B., boy, aged 6, was admitted to Mercy Hospital, May 22, 1913, on account of inability to open his mouth more than half an inch. The boy was an eight months' child, born during a dry labor lasting twenty-four hours. It was early noticed that the child had difficulty in nursing but the reason for this was not discovered. When the boy was 18 months old, the mother noticed that the right side of the face was deformed, that is, it was flattened. The left side appeared to be full and round. About this time the boy had *pneumonia* and when the attending physician attempted to introduce a spoon into the mouth for the purpose of examining the throat, he was unable to do so. When the boy was 3 years of age, his mouth was pried open and a cork was placed between the teeth. As soon as the cork was removed, however, the jaw immediately closed down to half an inch. The patient has never had any other illness than the pneumonia; no nose, throat or ear trouble, and no injury. He has been fed through a gap made in the upper and lower dentures by the extraction of a tooth in each.

Examination.—The physical deformity was striking (Fig. 15). The left side of the face was full and round. The right side was flattened over the body of the inferior maxilla. The mouth was slightly twisted; the chin was displaced to the left of the median line and receded. The patient could open his mouth for a distance of only half an inch (Fig. 16). There was a slight anteroposterior sliding motion in the right temporomaxillary articulation. There was *no* lateral motion whatever. The roentgenograms, one showing the mouth closed and the other open, were somewhat indistinct. The articulation was not clearly outlined, but the coronoid process seemed to change position when the mouth was open, so that I concluded that it was probably only a fibrous ankylosis of the left temporomandibular articulation, an opinion confirmed at operation.

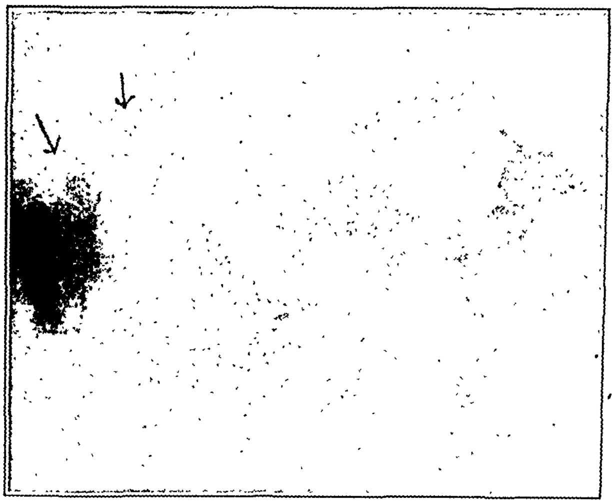

Fig. 13 (Case 2).—Roentgenogram of right side of head made before operation, showing the complete obliteration of the temporomandibular articulation.

Operation.—May 23, 1913, the articulation was exposed by means of the perpendicular incision made immediately in front of the ear, extending from a point half an inch below the zygoma, upward into the hair-line for a distance of 2 inches. By retracting the wound edges the articulation was easily exposed. On moving the jaw it was found that the coronoid process was free, but that there was a fibrous ankylosis between the head of the mandible and the fossa. By means of a scalpel and a narrow quarter-inch straight carpenter's chisel the ankylosis was divided and about ⅓ inch of the head of the bone was removed, so as to make room for the interposing flap, which was reflected from the temporal muscle aponeurosis in the usual manner. The flap was 1½ inches in length and ¾ inch wide. It was dropped down over the zygoma into the joint, so as to cover the raw bony surface of the condyle. It was fixed in place by means of two tacking catgut sutures, one at each basal angle of the flap (Fig. 7). The skin wound was then closed in the usual manner.

Result.—On the morning of the following day the boy had free motion in the jaw in spite of the fact that there was a considerable edema of the left side of the face, especially of the field of operation. The stitches were removed on the ninth day. Primary wound healing occurred. The edema rapidly subsided and motion increased to such an extent that when the patient left the hospital, about three weeks after the operation, he could open his mouth easily a distance of and inch and a quarter (Fig. 17). A report received April 4, 1914, reads as follows: "The result I am sure will please you, as it is a perfectly splendid one" (Fig. 18).

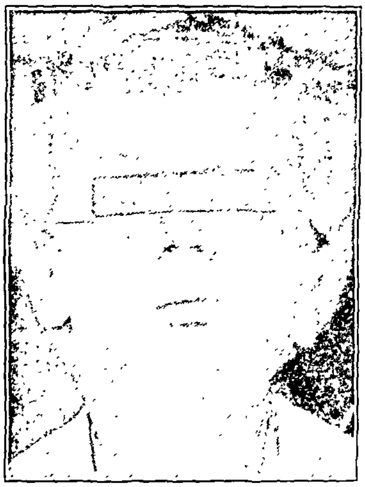

Fig. 15 (Case 3).—The fulness of the left side of the face, the flattening to the right of the chin and the displacement of the latter to the left are very evident.

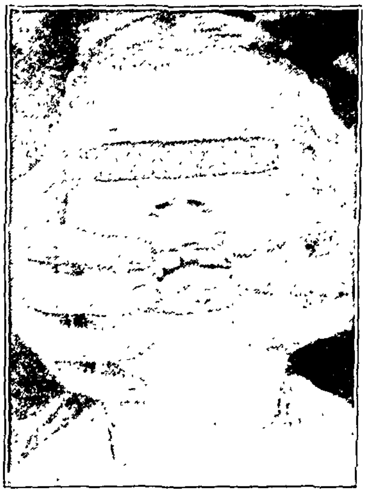

Fig. 16 (Case 3).—The extent to which the mouth could be opened and the gap in the denture through which the patient was fed.

This is the only case in this series in which there was an extensive edema of the face following the operation. The swelling was enormous and was undoubtedly caused by the manipulation of the tissues, and while it temporarily prevented active efforts on the part of the patient to move his jaw, it did not interfere with the final result, which was splendid. This, too, was the only case of intra-articular fibrous ankylosis. It did not involve the coronoid process which was free, as shown in roentgenograms of the mouth opened and closed. It will be noted that the operation which was performed in this case is similar in principle to that performed in the cases of bony ankylosis.

Case 4.—*Ankylosis of Left Temporomandibular Articulation.*—D. C., boy, aged 13, was admitted to Mercy Hospital, June 6, 1913, because of complete fixation of the lower jaw. In September, 1909, the patient fell from a third-story window a distance of 45 feet, landing on a brick pavement. He alighted on his feet, but his knees were flexed forcibly and the body bent forward, so that the chin impacted with the knees. The result was two lacerations of the skin over the chin and several broken teeth. He was picked up unconscious, bleeding profusely from his nose, mouth and ears. He was taken to the hospital and remained unconscious for three hours. When he left the hospital on the sixth day he was unable to open his mouth. His jaw was fixed and has remained so ever since.

Examination.—The right side of the face is slightly flattened. The left side is full and round. He is unable to separate his teeth at all, but because of the retraction of the chin, which is considerable, he is able to feed himself. There is a space of about a half inch on a horizontal line between the upper and lower teeth. Diagnosis: Bony ankylosis of the left temporomandibular articulation (Figs. 19 and 20).

Operation.—June 7, 1913, an incision was made along the upper border of the zygoma, extending from the ear forward on the cheek for a distance of about ¾ inch. The skin flap was displaced downward, and the articulation was exposed. A bony ankylosis extending from the condyle to the coronoid process was found. By means of the straight ¼-inch chisel, the ankylosis was freed and ⅓ inch of the condyle and of the coronoid process was removed. The jaw then dropped down freely. A second perpendicular incision was then made extending from well up in the hairy portion of the scalp downward in front of the ear to the starting-point of the first incision. This gave ready access to the temporal muscle and fascia. The usual flap was raised, dropped down over the zygoma and tucked into the joint, so as to cover all raw bony surfaces. Fixation was maintained by means of two tacking sutures of catgut placed in the angles of the flap. The skin wounds were closed in the usual manner.

Result.—The day following the operation the boy opened his mouth voluntarily for the first time in nearly four years. He rapidly increased the range of motion by means of the wooden wedge which I use in all of these cases and by chewing gum. The stitches were removed on the eleventh day. Primary wound healing occurred. When the patient left the hospital, two weeks after the operation, he opened his mouth freely about an inch and a quarter (Figs. 21 and 22). When the boy was seen again, first about six months afterward and again nine months afterward, he had almost complete limitation of motion of the lower jaw, the result of neglect to carry out the prescribed after-treatment by means of the wooden interdental block. There was no return of the bony ankylosis, however.

This was the only case in this series, except Case 2, which occurred in an adult, in which the ankylosis was comparatively recent and did not come on early in life. It was the result of a distinct and definite trauma and not of an infection. When the articulation was exposed, I could find no trace or evidence of the fracture into the joint, but the history would lead to the belief that there must have been a traumatic fibrous arthritis with subsequent ossification. This is the usual course that follows blows on the chin. The same type of ankylosis occasionally occurs in the elbow-joint when youngsters fall and strike severely on the olecranon.

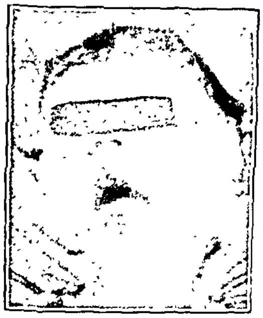

Fig. 17 (Case 3).—Thirteenth day after the operation; extent to which the patient could open his mouth.

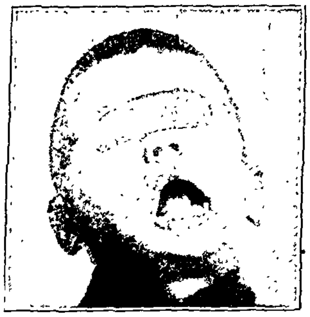

Fig. 18 (Case 3).—Degree to which the patient could open his mouth voluntarily eleven months after operation.

Case 5.—*Bony Ankylosis of Left Temporomandibular Articulation.*—F. C., boy, aged 7, was admitted to Mercy Hospital, June 13, 1913, because of complete fixation of the lower jaw. He was an orphan and little of his history could be obtained. His guardians stated that he had never been able to open his mouth since birth. They did not know anything about the labor. When he was a baby (age not given) he suffered for several months with a discharging ear (which one not known), but he had not been able to open his mouth before that time.

Examination.—It was impossible to separate the teeth. Several teeth had been extracted in the front of the boy's mouth to allow of his being fed (Fig. 23). On an attempt to pry the mouth open, a slight forward sliding motion was detected toward the left side. The left side of the face was full and round. The right side was flattened. The chin was slightly retracted, but the coaptation of the teeth was normal (Fig. 24). Diagnosis: Bony ankylosis of left temporomandibular articulation.

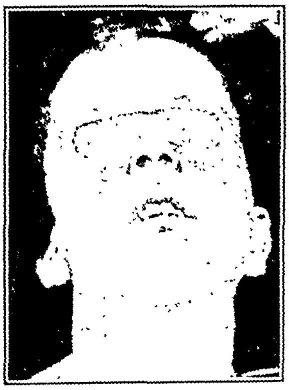

Fig. 19 (Case 4).—There was not much fulness of the left side of the face or much flattening of the right in this case, the ankylosis having existed for only four years, commencing at the age of 9. There is no deviation of the chin, although there is considerable retraction.

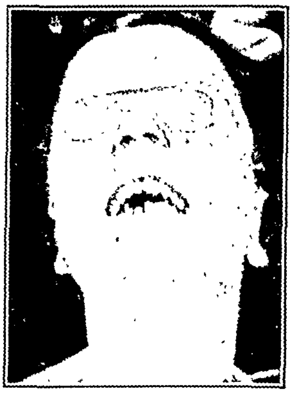

Fig. 20 (Case 4).—Extent to which the patient could open his mouth before operation.

Operation.—June 14, 1913, the articulation was exposed as in the previous case by means of the horizontal incision along the upper border of the zygoma and the perpendicular incision to expose the temporal fascia. It was found that the ankylosis was of the bony type and that it extended forward to the zygomatic tubercle. It was freed by means of a small olive-shaped dental burr, operated by an electric motor, and with a small bone-cutting forceps (Fig. 2, *C* and *D*) ⅓ inch of the condyle was removed. The jaw immediately dropped down. The flap of temporal fascia was then raised from the muscle and inserted in the usual manner. The flap was fixed by means of two tacking catgut sutures placed at its basal angles. The wound was closed in the usual manner.

Result.—On the following morning the boy could open his mouth for about half an inch. Motion was encouraged by means of the wooden wedge, which was inserted between the molar teeth. The stitches were removed on the tenth day. Primary wound healing occurred. When the patient left the hospital on the sixteenth day he could open his mouth easily an inch and a quarter (Fig. 25).

On May 16, this patient returned to the hospital with a complete fixation of the jaw. Examination indicated that there was a bony ankylosis. On the 18th an incision was made similar to the original one and it was found that a complete bony ankylosis had recurred and had extended forward beyond the maxillary tubercle toward the coronoid process. All of the bone was excised, leaving a cavity of ½ inch. A small connective tissue and fascia and fat flap was prepared with the base attached to the cheek tissues below the mandible. This was inserted and fixed by the angular tacking stitches as in previous operations, and the wound was closed in the usual manner.

All of the previously interposed flap had entirely disappeared, probably due to the pressure on account of the failure to maintain the interdental block in the usual way. The day following the operation, the patient had no trouble in opening his mouth voluntarily for ¾ inch.

Case 6.—*Bony Ankylosis of Left Temporomandibular Articulation.*—E. F., girl, aged 8, was admitted to Mercy Hospital, July 10, 1913, because of inability to open her mouth for more than ¼ inch. When she was 2½ years old she had a cold, but was not ill enough to be put to bed. After two or three days she had severe earache on the left side, and a swelling appeared in front of and behind the ear. A week later she had an abscess in front of the ear at the maxillary articulation. The swelling around the ear became larger, very painful and tender, especially in front of the ear. The patient could open her mouth at this time and had no pain when moving the jaw. One week later the left ear began to discharge pus very freely and she also had a very bad diarrhea. She was very ill and had a high (?) temperature. The pain was so severe that in her delirium she pulled out her hair on that side of the head. The swelling around the ear increased in size and extent until the whole side of the face was involved and discolored. Five weeks after the abscesses formed, she was operated on (April 21, 1908). The abscess in front of the ear and the one into the maxillary articulation were opened and drained and the mastoid operation was performed. The wound into the maxillary articulation drained for two weeks; that in front of the ear continued to discharge pus for three months after the operation. The mastoid wound discharged pus for six months, during which time four operations were performed, more bone being removed each time. Following the last operation in October, 1908, the wound closed rapidly.

April 28, 1908, one week after the abscesses were opened, the mother noticed that the baby could not open her mouth more than she can at present. The fixation has remained in spite of repeated attempts at stretching.

Examination.—There was not much deformity in this case (Fig. 26). There was a little fulness on the left side of the face and a slight flattening on the right. The chin was almost in the median line and only slightly retracted. The mouth could not be opened more than ⅛ inch (Fig. 27). The roentgenogram (Fig. 28) of the left side of the face showed entire obliteration of the temporomandibular articulation. Comparing this with the roentgenogram of the right side (Fig. 29), the difference between the two was quickly noted. Diagnosis: Bony ankylosis of the left temporomandibular articulation.

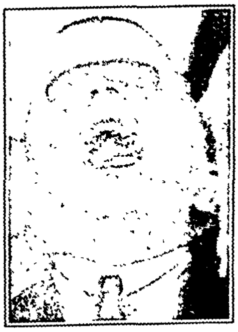

Fig. 21 (Case 4).—About two weeks after operation; extent to which the patient could open his mouth voluntarily.

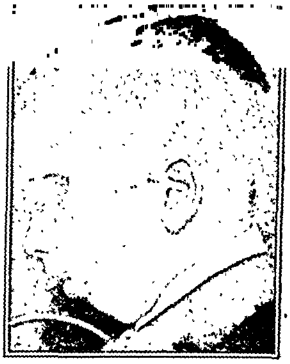

Fig. 22 (Case 4).—Skin wound two weeks after operation. This is a good illustration of the type of incision usually employed in these cases. The retraction of the chin shows very well in this picture.

Operation.—July 12, 1913, the left temporomandibular articulation and the temporal muscle were exposed by means of the L-shaped incision used in the two previous cases, that is, a horizontal incision extending along the upper border of the zygoma and the perpendicular incision in front of the ear, extending upward into the hair. When the articulation was exposed, the diagnosis was confirmed. The ankylosis was freed with the olive-tipped dental burr, as in the previous case. One-third inch of the upper end of the condyle was removed with bone-cutting forceps. As soon as the ankylosis was freed, the jaw dropped down. A flap of temporal fascia and muscle, measuring ⅝ inch in width and an inch and a half in length, was elevated from its bed, and dropped down over the zygoma and into the articulation, so as to cover all raw bony surfaces. Two catgut sutures placed at the basal angles of the flap secured its fixation. The wound was closed in the usual manner.

Result.—The following morning the patient had motion in the jaw, being able to separate the teeth for about half an inch. She was given the wooden wedge to use and when the stitches were removed on the tenth day, she was able to open her mouth for an inch. The wound had healed by primary union, but there was a slight collection of fluid underneath the skin above the zygoma. Three days later when the second dressing was made this fluid was removed by aspiration. It was a dark-colored, clear, odorless fluid, the result of oozing. The fluid did not reform and the patient left the hospital fifteen days after the operation. She was able to open her mouth fully an inch. She returned for examination on the twenty-second day. She could open her mouth easily for a distance of more than an inch and a quarter (Fig. 30). A photograph received six months after the operation shows that she has perfect use of her jaws (Fig. 31).

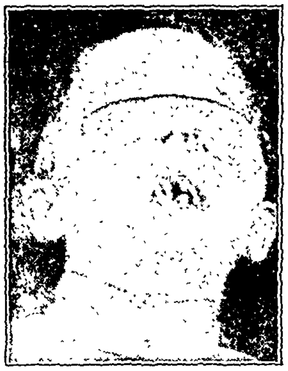

Fig. 23 (Case 5).—Absolute fixation of the jaw and the gap in the denture through which the patient was fed.

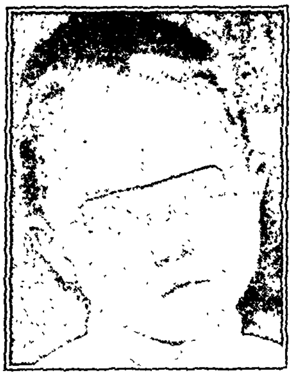

Fig. 24 (Case 5).—Bony ankylosis of the left temporo-mandibular articulation, with fulness of the left side of the face and some flattening of the right side over the body of the jaw. The chin is slightly deviated to the left.

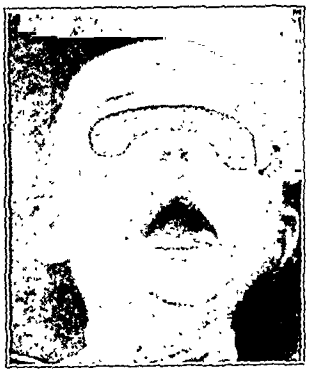

Fig. 25 (Case 5).—Photograph made about two weeks after operation, showing how well the patient could open his mouth.

This was one of the three cases in this series in which a hematoma developed after the operation. The hemorrhage during these operations is very slight, and there is little necessity for ligating bleeding vessels; but I am always very careful to ligate every bleeding point, because my experience in my arthroplasty work on the larger joints has taught me that that is the safest procedure, if one would avoid the occurrence of hematomas, which materially hazard the subsequent course of the case.

Case 7.—*Ankylosis of Left Temporomandibular Articulation.*—L. J., man, aged 31, was admitted to Mercy Hospital, Oct. 31, 1913, with ankylosis of both hips, all of the vertebral joints, including the occiput to the atlas, the left temporomandibular articulation and a partial ankylosis of both shoulders.

In July, 1895, the patient fell from a horse, striking the ground forcibly with the lower end of his spine. He was able to get up immediately and walk, but he had severe pain in the spine. This persisted for several days and then disappeared entirely. In the spring of 1896, he had severe pains in the right hip, the pain coming on slowly and increasing in severity, without any other symptoms referable to the hip. He asserts that he was not subject to tonsillitis or other infections in his nose, mouth, accessory sinuses or elsewhere, either at this time or previously. He consulted a physician, who examined him and discovered a marked scoliosis in the lumbar region. He walked without any support, however, but limped slightly. Some time during 1897, a plaster-of-Paris body-cast was applied to correct the scoliosis. He wore this cast for four years, when a leather jacket was substituted, and this too was worn for four years. During all of this time the right hip became more stiff but less painful. In 1903 he was forced to use a cane, as the right hip was very stiff. In the latter part of 1903, he began to have attacks of pain in the back of the neck, increasing on motion of the head. Finally the neck became stiff, so that he was unable to turn the head in any direction or bend his neck. In March, 1906, the left hip became painful and he was forced to resort to crutches. In June the left temporomandibular joint became affected and gradually power of motion in this joint was lost. The pain disappeared with the loss of motion. In September, 1906, the patient discarded his crutches permanently and not until then did he notice that he could not raise his arms to the full extent. He denied all previous illness, except typhoid at the age of 7; he said that there had been no lues and no neisserian infection.

Examination.—The spine was ankylosed from top to bottom. Both hips were stiff. Motion in the shoulders was restricted in every direction. The lower jaw was absolutely fixed, so that the patient could not open his mouth at all. His head was acutely flexed forward, the chin almost resting on his chest. The conformation of his face indicated clearly that the left temporomandibular articulation was ankylosed. He had had several of his lower teeth extracted, so that he could take food. The right side of the face was flat; the left side was full and round and the lower jaw was slightly retracted.

Operation.—Nov. 10, 1913, the usual arthroplasty for this condition was done, except that instead of an attempt being made to separate the ankylosis with the chisel, the neck of the bone was divided, because there was so much new bone formation in the joint that it was feared that if an attempt were made to seperate the ankylosis the underlying structures might be injured. Therefore, a new joint was made by dividing the neck of the condyle, allowing all of the head to remain in the fossa. The interposing flap was taken from the fat and fascia over the temporal muscle, and because of the sparsity of fat some of the muscle-fibers were removed with the flap. The flap was dropped down over the zygoma into the new joint and tacked with catgut sutures at its basal angles in the usual manner. There was much bleeding in this case and great care was taken to ligate every bleeding point. The wound was closed as usual.

Result.—The first dressing was made, November 22. The wound had healed by primary union and the stitches were removed. There was a considerable hematoma, however, under the skin over the temporal region. Two ounces of a clear, port-wine colored, odorless fluid were removed by aspiration. Microscopic and bacteriologic examination of this fluid was negative. It was aseptic. Two days later another aspiration was made, only half an ounce of fluid being removed. This fluid was likewise negative bacteriologically. The subsequent course of the case was uneventful. The range of motion increased rapidly from half an inch the day following the operation to about ¾ inch on leaving the hospital. The range of motion was limited by the impingement of the chin against the chest. The patient could masticate freely and regarded it as a great pleasure.

Case 8.—*Bony Ankylosis of Right Temporomandibular Articulation.*—M. Van W., girl, aged 11, was admitted to Mercy Hospital, Nov. 6, 1913, because of inability to open her mouth. When 2½ years of age she had a very severe illness lasting from five to six weeks. Her father stated that she had had a sore throat and expectorated purulent material. When she recovered, her jaws were stiff, but she could still open her mouth a little. Six months later she had a boil on the back of her left hand, next, one near the left elbow, then one in the left axilla, one on the left side of the neck and one on the right leg. All of these boils were lanced as they appeared and all discharged pus for a while and then healed. The limitation of motion in the jaw increased in degree until four years ago, when the jaw became absolutely stiff, the teeth being clenched together. The patient is said never to have had any trauma of the face or any other illness except the one mentioned.

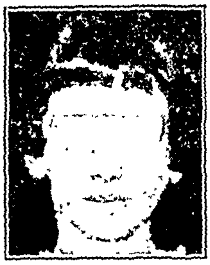

Fig. 26 (Case 6).—There was very little deformity in this case, just a slight deviation of the chin to the left.

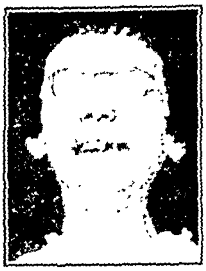

Fig. 27 (Case 6).—Extent to which the patient could open her mouth before operation.

Examination.—There is absolute ankylosis of the right temporomandibular articulation, bony in type. The right side of the face was full and round, the left side was flattened. The chin was retracted and drawn slightly beyond the midline to the right. There was no motion whatever in the jaw. *Diagnosis:* Bony ankylosis of the right temporomandibular articulation (Fig. 32).

Operation.—Nov. 15, 1913, the usual operation was performed, the joint being exposed by means of the L-shaped incision. The ankylosis involved the head of the condyle. The bones were divided with a narrow straight chisel in such a manner as to retain the normal conformation of the joint as much as possible. The gap for the interposing flap was about ⅓ inch in width. As soon as the ankylosis was divided, the mouth could be opened easily by the anesthetist, although the stiffness of the muscles and ligaments on the other side prevented the lower jaw from falling down. The pedicled flap of fat and fascia was raised from over the temporal muscle. It was an inch and a half long and an inch wide. It was dropped down over the zygoma into the joint and was secured by tacking catgut sutures at its basal angles. The wound was closed in the usual manner.

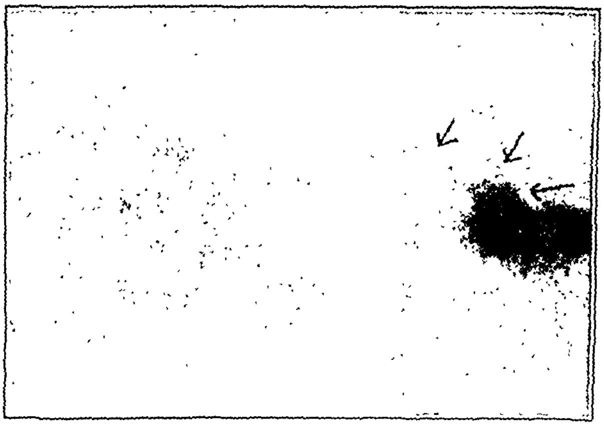

Fig. 28 (Case 6).—Roentgenogram of left side of head made before operation, showing complete obliteration of the temporomandibular articulation. Compare with Figure 29.

Result.—The following morning, this patient, like all the others, could open her mouth easily more than half an inch. The range of motion increased rapidly and when she left the hospital three weeks after the operation the spread of the jaws measured an inch and a quarter. The wound had healed by primary union with no complications. A photograph received from this patient four months after the operation shows a superlatively good result (Fig. 33).

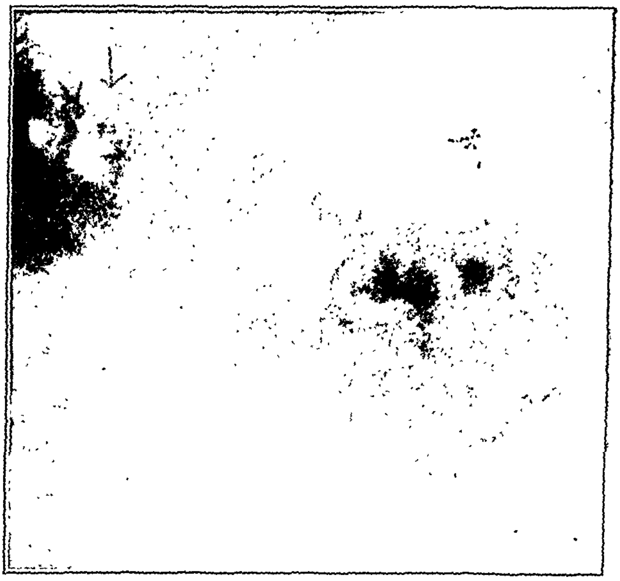

Fig. 29 (Case 6).—Roentgenogram of right side of head made before operation, showing a normal temporomandibular articulation.

Case 9.—*Bony Ankylosis of Right Temporomandibular Articulation.*—J. S., man, aged 25, was admitted to Mercy Hospital, Nov. 11, 1913, because of ankylosis of the right temporomandibular joint and the right hip, with a discharging sinus over the right clavicle and another in the right groin. In 1905, after he had been swimming, he had a chill and immediately afterward he noticed a stiffness in the right knee but no pain, redness or swelling. He does not know whether or not he was subject to an infection in any part of his body at this time, nor had he sustained a trauma. He was able to use his knee without pain or discomfort. The following morning he was awakened by severe pain in the left knee and on examination he saw that it was red and swollen. A physician was consulted immediately, who made a diagnosis of abscess in the knee and prescribed hot fomentations. The following day the pain in the knee was very severe and the joint was greatly swollen. He had a high (?) fever and became delirious. He was removed to

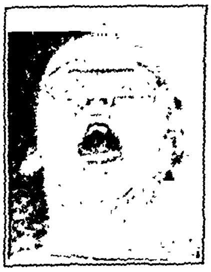

Fig. 30 (Case 6).—Extent to which the patient was able to open her mouth voluntarily, twelve days after the operation.

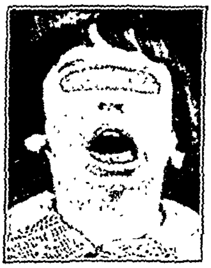

Fig. 31 (Case 6).—Photograph made six months after operation, showing a splendid spread of the jaws.

a hospital, the leg was incised in several places and gauze wick drains were inserted. After the operation he was informed that the bone had been drilled into and found necrotic. He remained in the hospital about ten weeks with considerable elevation of temperature, and was delirious most of the time. The left hand and the left side of the neck had also been lanced and several incisions were made on the back along the spinal column. Pus was discharged from every opening. A large bed-sore developed over the left hip. When the patient left the hospital (he does not remember when), all the wounds had healed, except two in the left leg which were still discharging pus.

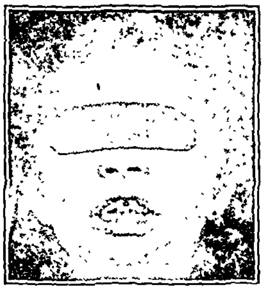

Fig. 32 (Case 8).—The jaw was firmly fixed, and there was the usual gap in the denture for feeding purposes.

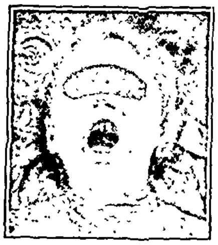

Fig. 33 (Case 8).—Front view four months after operation, showing the mouth open to nearly the normal degree and in a perfectly plumb line.

Two years later the left leg was amputated in the upper third of the thigh. About one month later he first noticed a stiffness in his jaw, but there was no pain in the temporomandibular joints. Four weeks later an abscess appeared over the left clavicle. It opened spontaneously and discharged pus freely and, he thinks, some necrotic bone. Abscesses also formed over the right clavicle and in the right axilla, and they too opened spontaneously and discharged pus. Finally all wounds healed.

In 1910 he began to have severe pain and swelling in the right arm. An abscess formed, was opened and necrotic bone removed and after a short period of discharge, the wound healed. The right elbow was the next joint to become involved, and when the inflammation in this joint had subsided, he was unable to move it. It was ankylosed. The abscesses in the right groin and over the right clavicle, which are still discharging, developed one year ago.

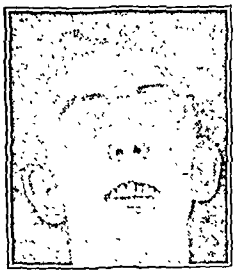

Fig. 34 (Case 9).—Ankylosis of right temporomandibular joint. The jaw is firmly fixed.

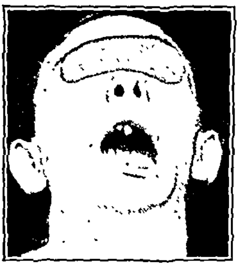

Fig. 35 (Case 9).—Four months after the operation the patient could easily open the mouth 1⅜ inches.

Examination.—The right elbow was firmly ankylosed and flexed to nearly right angles with the arm. The jaw was fixed. The teeth could not be separated even for a fraction of an inch (Fig. 34). The left side of the face was flat. The chin was retracted and drawn slightly to the right of the midline. Diagnosis: Bony ankylosis of the right temporomandibular articulation.

Operation.—What the patient most desired was to open his mouth so that he could feed himself. Therefore only the temporomandibular joint was operated on. Nov. 12, 1913, the usual arthroplasty was performed. The joint was exposed through an L-shaped incision. The ankylosis extended across to the tubercle and the usual interposing flap was placed. The wound was closed in the accustomed manner.

Result.—The morning after the operation the patient opened his mouth voluntarily about half an inch. The range of motion increased rapidly until at the time of the first dressing, made on the thirteenth day, he could open his mouth nearly an inch. The wound had healed by primary union. About 1 ounce of a clear bloody odorless fluid was removed by aspiration. Bacteriologic examination proved it to be negative. The stitches were removed on the thirteenth day. When the patient left the hospital, three weeks after operation, he could open his mouth about an inch and a quarter. The patient was seen again April 3, 1914. He could easily open his mouth 1⅜ inches without the slightest pain or discomfort. Lateral motion of the jaw was perfect and the scar was scarcely discernible (Fig. 35).

The facial nerve, which leaves the skull through the stylomastoid foramen, passing forward across the lower portion of the parotid, is distributed to all of the muscles of expression of the face, and there is danger of injuring that nerve and getting a permanent paralysis of these muscles, particularly the fibers that pass to the temporal and supra-orbital zones. These can all be avoided by the L-shaped incision above the zygomatic level.

There is another element of danger connected with this work, namely, one cannot divide the ankylosis in the line of the original articulation, because if he does he is almost certain to penetrate the base of the skull. Therefore, I always remove the condyle of the inferior maxilla and do not clean out the glenoid fossa to make a cavity.

The location of the internal maxillary artery must always be borne in mind in the removal of bone, as it hugs the neck on the inner side closely and can easily be injured. If it is injured, it should be ligated at the bifurcation of the external carotid. The importance of making the incision above the level of the zygoma can be recognized at once, as it puts the scar-line beneath the hair.

The after-treatment is very important. Mastication should be started at the end of two weeks, preferably not earlier, because otherwise too much fibrous tissue will be produced between the ends of the divided bones. The wooden block (Fig. 2 *E*) should be placed between the molars on the operated side and kept there day and night for two weeks, to prevent possible compression necrosis of the interposing flap. The jaw should not be spread at the time of the operation, as that lessens the effectiveness of the interdental block in protecting the flap.

In all my arthroplasty work there is no operation that gives the same satisfaction to the patients as that for ankylosis of the temporomandibular articulation.

2526 Calumet Avenue.

Accidents on Steam Railways.—According to Accident Bulletin No. 49 of the Interstate Commerce Commission the number of persons killed in train accidents during July, August and September, 1913, was 211; the number of persons injured was 4,011. These figures are compiled from the reports made in 1913 by the railways to the Interstate Commerce Commission. The total number of casualties of all classes amounted to 3,173 persons killed and 56,642 injured. This includes 2,830 persons killed and 19,763 persons injured as the results of accidents sustained by employees while at work, by passengers getting on and off cars, by persons at railway crossings, persons doing business at stations as well as by trespassers and others.

A CASE OF PSEUDOMYXOMATOUS CYST OF THE APPENDIX

HENRY HARTMAN, M.D.
AND
G. C. KINDLEY, B.S., M.D.
Professor of Pathology and Instructor in Pathology, respectively, University of Texas, Department of Medicine
GALVESTON, TEX.

Reference to the literature concerning retention-cysts of the vermiform appendix leads one to believe that either the condition is rather infrequent or many cases are not reported. In 1905, Corning[1] stated that only about sixty cases of cysts of this kind, discovered at operation or at necropsy, had been reported, and that in 7,108 necropsies by various observers there were found only twenty-seven cases (less than 0.4 per cent.). At the same time Corning reported four cases from among 735 appendixes removed at operation and sent to his laboratory. Since then a number of cases have been reported, particularly in the foreign journals. Thus Weinhold,[2] in 1909, removed a large appendiceal cyst from a woman aged 74, having previously made a diagnosis of pedunculated myoma of the uterus. Wilson[3] reports a case in which he had made a probable diagnosis of ovarian cyst, and another which ruptured during bimanual examination. Eden[4] encountered a case in which there was also a large cyst of the right ovary, which had ruptured. Recently, Hammesfahr[5] has described somewhat in detail his findings in two operative cases in which the contents of the cysts were pseudomyxomatous in character.

The formation of these cysts seems to be due chiefly to a chronic inflammatory process in the appendix, with obliteration of the lumen at the proximal end. Kinking of the organ and peritoneal adhesions may be causative factors.

In size, the cysts may range from very small to about 15 cm. long and 7 in diameter. The contents are generally described as thick, gelatinous, translucent material, which at times may be either blood-stained or greenish-yellow. It may be slimy or even watery in character. Most often the substance is made up largely of mucin or pseudomucin, but at times it may be colloid.

Usually the mucosa of the appendix has undergone marked atrophy or has disappeared. It may be pushed through the muscular coat in places to form with the serosa a false diverticulum.

The symptoms are commonly those of chronic appendicitis, but there may be no evidence of the trouble, not even a palpable tumor.

The importance of the condition depends on the possibility of rupture, which may give rise to the so-called pseudomyxoma of the peritoneum. According to Wilson,[3] only twelve cases of peritoneal pseudomyxomas arising in this way are on record; but Trotter[6] suggests that some cases with obscure symptoms may go unrecognized, and that others are regarded as examples of primary colloid carcinoma.

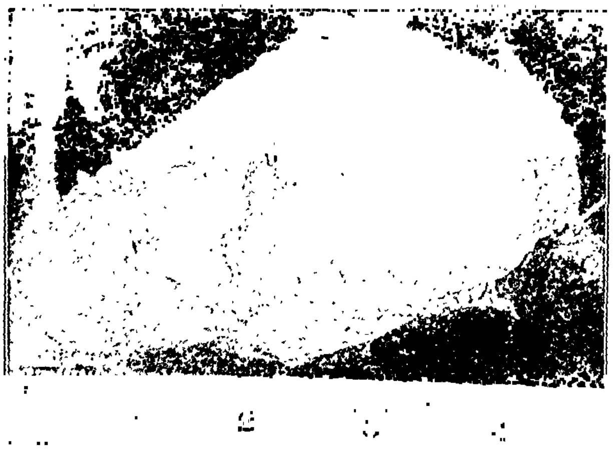
Through the courtesy of Dr. A. O. Singleton, who operated on the patient, we wish to report a case of unruptured, pseudomyxomatous cyst of the appendix.

History.—C. T., negress, aged 48, married, housewife, rather obese, consulted Dr. Singleton in August, 1913. According to the patient the present illness began two years previously, characterized by irregular attacks of pain and discomfort in the right iliac region. Six months before seeing Dr. Singleton she was operated on, she said, for movable kidney, but she did not know what the operator really did. No relief was afforded by the operation.

Examination.—A distinct operative scar was found in the right lumbar region. Palpation revealed a large movable mass in the abdominal cavity, on the right side, but owing to the thickness of the abdominal wall, no additional information could be gained. Diagnosis, probably a floating kidney.

Operation.—This was performed, Sept. 3, 1913. After an incision had been made in the right lumbar region, the kidney was found to be normal and fixed. So the incision was extended and the peritoneal cavity opened. This revealed a large cyst of the appendix, extending upward, free from adhesions, and with a stump of apparently normal appendix about 3.5 cm. long. For about one-third of the length of the cyst there was a distinct mesentery. An ordinary appendectomy was performed. Recovery was uneventful, and since the operation (eight months ago) the patient has been in good health.

Gross Appearance of Cyst.—This measured 11 cm. in length and 5 in its greatest diameter, that is, near the proximal end. The surface was white and irregular, and the contents seemed to be held under slight pressure. It was fixed several days in formaldehyd solution, and then cut open. Thick, white, rather opaque, gelatinous material filled the cyst. This could be picked up in jelly-like masses with the fingers. Chemically the material seemed to be pseudomucin, as portions were dissolved in sodium hydroxid and not precipitated by an excess of acetic acid. The wall of the cyst varied in thickness from 1 to 4 mm. Apparently, dark-colored bits of tissue were embedded here and there in the contents, especially in the distal portion. Keeping the specimen in formaldehyd solution soon caused the contents to swell, so that the edges of the cut wall gaped widely.



Pseudomyxomatous cyst of appendix.

Microscopic Appearance.—Sections of the appendix near the cyst showed normal muscular coats with marked proliferation of submucosal tissue, so that the lumen was entirely obliterated. Sections of the cyst wall, taken from several different places, showed practically nothing but dense fibromuscular tissue, much of which had undergone hyaline degeneration. The nuclei of the peritoneum and of the connective tissue beneath were usually fairly well preserved. In no instance could epithelium be found, except the desquamated bits out in the cystic contents. The mucoid material itself, taking a light hematoxylin stain, was seen to be finely granular and at times fibrillar, with numerous irregular, open spaces.

THE EARLY DIAGNOSIS OF LEAD-POISONING *

HARRY LINENTHAL, M.D.
Assistant Physician to Outpatients, Massachusetts General Hospital; State Inspector of Health
BOSTON

The subject of occupational diseases has of late been attracting considerable interest. We are coming to a realization that diseases caused by industrial poisons or conditions under which industries are carried on have a marked influence on the morbidity and mortality of the community. What is of still greater importance, we recognize that such diseases are, at least in a very large measure, preventable. Since 1911 fourteen states of the Union have enacted laws requiring physicians to report to designated state authorities occupational diseases which they are called on to treat. The lists of these occupational diseases in the various states are not uniform, but most of them contain such conditions as poisoning from lead, brass, phosphorus, arsenic or mercury or their compounds; or from wood alcohol, anthrax or compressed-air illness.

In view of the fact that physicians of many states are now required to report the above-named occupational diseases, it is pertinent to inquire as to their early diagnosis. When can a diagnosis be made sufficiently definite to warrant the physician in reporting it to the proper authorities? Of all the diseases in the list none is of so common occurrence as is the poisoning due to lead or its salts, on account of the great variety of industries in which the metal or its salts are used. I therefore propose to consider the early diagnosis of plumbism the most common and by far the most serious in its effects on the health of the working population.

Lead-poisoning presents itself in a great variety of manifestations, and while the diagnosis in a well-marked case is usually not difficult, it may not be so clearly defined in the early stages of the intoxication. The tendency in such cases is not to make the diagnosis unless the objective signs are found which are supposed to be pathognomonic of the disease. This tendency to postpone the diagnosis in the absence of certain objective signs is dangerous and often does incalculable harm. The physician who fails to recognize tuberculosis, for instance, without the presence of tubercle bacilli in the sputum, very often fails to avail himself of the opportunity of arresting the disease in its incipiency. The same is true of lead-poisoning. The waiting for certain signs before establishing the diagnosis may permit the poison to undermine the constitution of the worker beyond any remedial measures. The objective signs supposed to be pathognomonic of lead-poisoning, the presence of one or more of which is still regarded by many physicians as absolutely necessary before a diagnosis can be made, are the lead-line on the gums, basophilic degeneration of the red cells and the presence of lead in the urine and stools.

The technical difficulty of the last one is so great as to preclude it from being made a part of the routine examination in general practice. Moreover, the presence of lead in the excretions is not constant even in well-marked cases of lead-poisoning. On the other hand, lead has often been found in the urine and more frequently in the stools of persons exposed to lead who do not show any evidence of intoxication.

OVEREMPHASIS ON LEAD-LINE AND BASOPHILIC GRANULES

The presence of the lead-line, and basophilic degeneration of the red cells, are objective findings which are in practical use in the diagnosis of lead-poisoning. As a matter of fact, neither one of these signs is pathognomonic of the disease, and while their presence is a valuable aid in the diagnosis of obscure cases, their absence should not be given undue weight against the diagnosis of lead-poisoning, when a history of definite exposure to lead can be obtained.

Basophilic granules in the red cells may be found in severe secondary anemias in which hemolysis has taken place, and are, on the other hand, often absent in cases in which a positive diagnosis of lead-poisoning can be made. In looking over a large number of records in which a definite diagnosis of lead-poisoning was made in the Outpatient Department of the Massachusetts General Hospital, by the clinical symptoms and the presence of the lead-line, I found that in nearly 50 per cent., basophilic granules in the red cells were absent.

Sir Thomas Oliver, who has devoted a great deal of time to the study of lead-poisoning, states that in only few instances of the great number of examinations of the blood that he has made, in early as well as in late cases of plumbism, has he found the basophilic granules. Basophilic degeneration of the red cells, in short, does not possess the diagnostic value which some attribute to it, but can at most be regarded as an important confirmatory sign.

Still greater importance is attached to the presence of the lead-line.

In my investigation of some of the lead industries of Massachusetts several years ago, for the State Board of Health, I had occasion to confer with many physicians who, from time to time, treated patients engaged in these industries, and I frequently found that no matter how suggestive the symptoms complained of were of lead-poisoning, the diagnosis was not made because of the absence of the lead-line. As a matter of fact, the lead-line presents a great many anomalies, and irreparable harm will often be done when a diagnosis of plumbism is not made because of its absence. In the investigation referred to above, I have frequently seen well-marked lead-lines among workers exposed to lead who did not present, at the time of investigation or at any previous time, any signs of ill health. On the other hand, if one looks into the very extensive literature on the subject, one will find many cases of severe lead-poisoning reported in which lead has been definitely demonstrated in the urine and stools, and yet no vestige of a lead-line could be found. Moreover, the lead-line is extremely rare when the gums are in a healthy condition and when the teeth are well cared for. Dr. Oliver fed experimental animals with lead for a long time without observing any lead-line. If, however, an infection of the gums of such animals was produced, the lead-line appeared within a short time.

The distinction between lead absorption and lead-poisoning is not, as a rule, clearly borne in mind. All persons working in lead, unless the most unusual pre-

---

* From the clinic of the West Medical Service, Massachusetts General Hospital.

cautions are taken, inhale or swallow some of the poison, but it is excreted through the kidneys and the intestinal tract. As long as the excretion corresponds to the absorption, no symptoms will manifest themselves. If, however, for some reason, the balance is destroyed and the excretion diminishes, lead will be stored up in the tissues and poisoning is the result. The presence of the lead-line simply means that the person has been absorbing lead, and is in itself of no greater weight in the diagnosis of lead-poisoning than is the fact that the patient's history shows that he is working in a lead process, in which we know that he inevitably absorbs lead. A careful inquiry into the nature of the industrial process in which the patient is engaged is therefore of the utmost importance. The history of exposure is the all-important factor in the diagnosis of plumbism.

In cases of non-industrial plumbism, however, in which no history of exposure can be obtained, the presence of the lead-line or of the basophilic granules is of inestimable value in the diagnosis, since it offers a clue for the explanation of certain symptoms which would otherwise be obscure.

The following case-reports, taken from the records of the Massachusetts General Hospital will illustrate the reluctance, even among good clinicians, to make a diagnosis of plumbism in the absence of the lead-line, or stippling:

CASE 1.—A man of 36, a sheet-metal worker for eleven years, handles a great deal of lead in his work, complains of pains in the abdomen, loss of weight, weakness of extremities and attacks of diarrhea followed by constipation. No lead-line.

CASE 2.—A man of 34, a painter for ten years, complains of attacks of colic, headaches, obstinate constipation and general nervousness. No lead-line, no stippling.

CASE 3.—A man of 22, a painter for four years, complains of constipation, attacks of severe abdominal pains and headaches. He looks pale; no lead-line, no stippling.

CASE 4.—A painter of 22, who has worked at the trade for ten years, complains of obstinate constipation, pain in his joints, headaches, numbness and weakness of extremities; he is easily fatigued; no lead-line or stippling found.

CASE 5.—A worker in a rubber factory for six years complains of abdominal pains, obstinate constipation, severe pains in lumbar region, loss of appetite, and general nervousness; no lead-line found.

CASE 6.—A man of 49, a painter for twenty-five years, gives a history of lead-poisoning when he first started his work. He now complains of tremor and weakness of hands so that he frequently drops his brush while at work. He has attacks of abdominal pains, pains in his joints, and is pale. No lead-line or stippling found.

CASE 7.—A man of 38, who worked in a car-factory for fourteen years, and part of whose work consisted of mixing lead, complains of sharp pains in the abdomen, attacks of dizziness, fine tremor of hands, metallic taste in the mouth and pains in the extremities. He lost considerable weight. No lead-line or stippling found.

In none of the foregoing cases was a definite diagnosis of lead-poisoning made. There is no doubt, however, that if a lead-line was present in any of these cases, or if stippled red cells were found, even if the symptoms had been less characteristic, a positive diagnosis of plumbism would have been made. Yet the occupation of these patients was sufficient evidence that lead absorption was taking place, and the symptoms were sufficiently characteristic to warrant a definite diagnosis without the corroborative evidence of the lead-line or stippling.

In consequence of the undue weight which is given to the objective signs, persons who show themselves, by the symptoms of which they complain, susceptible to the influence of lead, are permitted to continue at their work without any additional precautions and without any warning as to the danger to which they are exposed. This is shown by the following illustrative case-reports, taken from the records of the outpatient department of the Massachusetts General Hospital. These patients attended the clinic for a long time, and no diagnosis of plumbism was made because of the absence of the lead-line or stippling. At some later date, however, although the symptoms were the same, the diagnosis of plumbism was made because of the appearance of one or more of the objective signs.

CASE 8.—A worker in a rubber factory came to the clinic complaining of precordial pains, headaches, pains in the arms and attacks of abdominal pains. He had evidence of mitral regurgitation. There was no lead-line, and no diagnosis of lead-poisoning was made. He came again eight months later with the same symptoms but of increased severity. A lead-line was found present at this time, and a diagnosis of plumbism was made.

CASE 9.—A painter of 23 came to the clinic, November, 1907, complaining of pain in the back, numbness and weakness of extremities, abdominal pains, headaches and nervousness; no lead-line was present, and no diagnosis was made. In 1912 he presented himself with the same symptoms. Lead-line and stippling were found and a diagnosis of lead-poisoning was made.

CASE 10.—A painter presented himself at the clinic in July, 1907, complaining of constant severe pain in the upper abdomen, attacks of vomiting, pains in the knees and dizziness. A diagnosis of arteriosclerosis was made. In July, 1913, he presented himself again with the same symptoms. A lead-line and stippling were found. Diagnosis, lead-poisoning.

CASE 11.—A machinist of 28 came to the clinic in 1906, complaining of attacks of severe abdominal pains, bad taste in the mouth, obstinate constipation, attacks of nausea and vomiting. He came many times during 1910 and again in 1911, complaining of the same symptom-complex. In December, 1911, a lead-line was found and many stippled cells. Diagnosis of lead-poisoning was made.

CASE 12.—A worker in a rubber factory, aged 57, came in 1904 complaining of pain in the cardiac area and the right shoulder, pains in hips and legs, weakness of extremities, dizzy spells, easily tired and constipated, also wasting of extensor muscles. No lead-line was found (patient had false teeth). No diagnosis of lead-poisoning was made until 1905, when lead was found in the urine.

CASE 13.—A carriage painter of 38 came in 1903 complaining of pains in the back between the shoulder-blades. There was no record of lead-line or stippling. No diagnosis was made. Later, in the same year, he came complaining of attacks of dull pain in the region of the umbilicus, and sharp pains in the lumbar region which kept him awake for two nights. A history of alcoholic excess was obtained for the last two weeks; no lead-line was found; diagnosis, alcoholism. In 1908 he came again, complaining of pains in his back and in his feet, general weakness and nervousness; no diagnosis was made. Several weeks later he came again complaining of the same symptoms. Lead-line was present at this time. Diagnosis of lead-poisoning was made.

The unwarranted delay so frequent in diagnosing plumbism even in the presence of a definite history of exposure to lead is well illustrated by the last case. For nearly five years this man had been presenting himself at various times at the hospital, complaining of a train of symptoms which, taken together with his work, should have made a diagnosis possible, and yet he was permitted, during all that time, to continue his work without any special precautions, until the lead-line appeared, when the diagnosis of lead-poisoning was made.

EARLY SYMPTOMS OF PLUMBISM

It would of course be folly to attribute to lead all the ill health of lead-workers. The symptoms, therefore, have to be considered carefully before the responsibility of the diseased condition is laid to the industry. The symptoms of early plumbism are not well defined, yet there is a group of symptoms which, when not open to explanation on any other basis must, when a history of exposure to contact with lead has been obtained, be taken as evidence of early lead-poisoning. Indeed, it is important to inquire carefully as to any possible industrial exposure to lead whenever certain ill-defined states of ill health present themselves among workers, when such diagnoses, for instance, as anemia, debility, constipation, lumbago or chronic arthritis are made. Inquiries as to the details of the patient's work should be made, for unless the physician has a familiarity with the various industrial processes, the general designation of the patient's work may not indicate any exposure to lead.

Among the earliest manifestations of chronic lead-poisoning is the pallor of the skin, which is often out of all proportion to the actual anemia — that is, the reduced hemoglobin and red count. Associated with this pallor is a wasting of the subcutaneous fat first noticed in the infra-orbital region and about the buccinator muscles, producing a pinched appearance of the face. General muscular weakness with "rheumatic" pains in the joints, muscles and more particularly in the back, are of frequent occurrence in the early stages of the disease. Among the gastro-intestinal symptoms are anorexia, nausea, attacks of constipation, or constipation alternating with diarrhea. Loss of appetite, from whatever cause, among workers exposed to lead is always a symptom to be taken seriously, for, as has been pointed out by Legge, the absorption of lead is greatly increased when the stomach is empty. The most frequent gastro-intestinal symptom is the more or less characteristic colic generally referred to the lower abdomen, which comes in paroxysms, and may or may not be associated with tenderness. General nervousness, persistent headaches and dull mentality are also among the earlier manifestations. These symptoms should always be regarded seriously when occurring in persons exposed to lead, for they may be the precursors to the more serious nerve-lesions, such as wrist-drop, encephalopathy and to the more insidious and less dramatic changes in the vascular and excretory systems, that of arteriosclerosis and chronic nephritis.

IMPORTANCE OF EARLY DIAGNOSIS OF OCCUPATIONAL DISEASES

The laws enacted in many of the states requiring physicians to report to a central authority certain occupational diseases are measures in the interest of the public health. These diseases are preventable, and the duty of the central authority to whom the reports are made is, or should be, to investigate the cases as they are reported, trace the source of the poisoning, instruct the patients as to precautions, and undertake preventive measures against the occurrence of other cases.

In occupational diseases, as well as in communicable diseases, the most effective weapon in the prevention of their frequent occurrence as well as in minimizing the serious consequences to the worker, leading to permanent injury to health and often terminating in death, is to discover these cases in their incipiency. This responsibility rests with the physician. He is in the vanguard in public health activity. It is through him that the public health authorities are made aware of the existence of preventable diseases, so that proper steps may be taken to detect and eradicate the dangerous spots which threaten the health and life of the community.

There is still another point of view which makes the recognition of occupational disease, whether it is due to lead or other industrial poisoning or conditions under which people are employed, of great importance. To remedy any social evil the first essential is to recognize its presence and its extent. It is only by a realization of the great amount of sickness and incapacity that is produced by occupational diseases that we can expect the proper remedial measures to be brought about. We have at present no available data of the extent of the well-defined specific occupational diseases, and still less adequate is our knowledge of the general effects of various industrial processes on the health of the workers. Our morbidity and mortality statistics, as far as their relation to occupation is concerned, are hopelessly inadequate.

The occupations recorded on hospital records are of little or no value as far as the study of the effects of occupation on health is concerned. The term "laborer," for instance, a designation assigned to a large proportion of the male outpatients, covers every conceivable kind of unskilled labor, and throws no light as to the nature of the work. The term "railroad worker" may mean a locomotive fireman, a gate-tender, or used as in a recent case which came to my notice, to designate the work of a young woman who was folding railroad time-tables in a printing-office.

A careful analysis and recording of the patient's work is essential not only for the diagnosis of the well-known occupational diseases, but also to extend our knowledge as to the effects of certain occupations on mortality and morbidity.

An intensive study in occupational diseases is now being carried on by Miss Susan Holton at the Social Service Department of the Massachusetts General Hospital under the direction of Dr. David L. Edsall. It is only by such intensive work that we may hope in time, by the accumulation of sufficient material, carefully investigated and recorded, to draw any inferences as to the effects of the various industrial processes on health.

SUMMARY AND CONCLUSIONS

The reporting of occupational diseases is a public health measure. Early diagnosis of these diseases is essential both to protect the worker from the more serious effects of the industrial poisons and to gather information as to the prevalence of these diseases.

In the diagnosis of plumbism, the most frequent of occupational poisoning, there is in many quarters a tendency to give too much emphasis to the presence of the lead-line or basophilic degeneration of the red cells. While the presence of these signs is often of great aid in the diagnosis of obscure cases of non-industrial origin, their absence should not prevent a diagnosis when certain symptoms characteristic of early plumbism manifest themselves, more particularly when a history of exposure to contact with lead can be obtained.

The history of exposure is the all-important aid in the diagnosis, and careful inquiry should be made by the physician as to the details of the patient's work, and he should not be satisfied with a general designation which may not give any indication of exposure to lead.

483 Beacon Street.

THE EFFECT OF INTRASPINAL INJECTIONS OF SERUMS WITH AND WITHOUT PRESERVATIVES *

JOHN AUER, B.S., M.D.
NEW YORK

It is an established fact that the administration of antimeningitis serum by intraspinal injection has practically turned the former 70 per cent. mortality from epidemic meningitis into 70 per cent. recoveries. Accumulated experience, however, has apparently shown that the injection of the serum itself may have been the cause of death in a very small number of cases. These deaths have been explained in a variety of ways, and of these I shall mention here only the statement of S. P. Kramer that they were caused by the trikresol which had been added as a preservative to the serum, a contention which has recently been supported by Hale[1] on the basis of experimental work on dogs and cats.

EXPERIMENTS WITH TRIKRESOL

Because of the importance of this matter I have carried out during the last few months a series of experiments not only with dogs, but also with monkeys, in order to determine what effects are produced when serums containing 0.3 trikresol, 0.3 per cent. chloroform or 0.3 per cent. ether are injected subdurally. As control injections, horse-serum without any preservative, and Ringer solution were employed. In all animals the blood-pressure was recorded either from the carotid artery (dogs) or from the femoral artery (monkeys); the respiration was registered in all by means of a pleural cannula. The intraspinal injections in the dog were made after a laminectomy had been performed, for the results without this were very uncertain; in monkeys, however, the subarachnoidean space was tapped exactly as in human beings by introducing a needle into the second to the fourth lumbar space. The dogs were maintained at a constant level of ether anesthesia by intratracheal insufflation, a procedure which absolutely prevents death from central respiratory causes. The monkeys were kept under ether anesthesia by means of an ordinary ether cone and received no respiratory aid whatsoever, but always breathed spontaneously. The chloroform and ether serums were not warmed before injection.

The results of these experiments are briefly as follows:

Dogs are much more sensitive to the intraspinal injection of 0.3 per cent. trikresol serum than monkeys, but dogs nevertheless tolerate up to 6 c.c. and more per kilogram without danger as a rule, provided that an efficient artificial respiration is maintained. In the dog, stoppage or impairment of the respiration is the great danger; the drop in blood-pressure, though often pronounced after larger doses, does not persist if the respiration is efficient.

ACTION IN MONKEYS

Monkeys, on the other hand, are relatively extremely resistant to 0.3 per cent. trikresol antimeningitis serum, and tolerate injections aggregating more than 6 c.c. per kilogram usually without any dangerous effect on spontaneous respiration. The blood-pressure generally shows a more or less decided drop, but the normal level is regained within some minutes. To illustrate the enormous quantities which a monkey can tolerate, the following experiment may be mentioned: A monkey of 2,835 gm. received intraspinally 21 c.c. of 0.3 *per cent.* trikresol antimeningitis serum (New York Board of Health), 23 c.c. 0.3 per cent. chloroform antimeningitis serum (Massachusetts Board of Health) and 10 c.c. of Ringer solution, and was in excellent condition at the end of the experiment. It is of interest that the same animal had received the previous day 6 c.c. trikresol serum and 15 c.c. chloroform serum intraspinally, and that on both days the respiration and blood-pressure were registered; moreover, on the second day the injections (usually 3 c.c. per dose, sometimes 5 c.c., at seven-minute intervals) were made while the animal had a full left-sided pneumothorax and was therefore not a normal animal.

Both in the monkey and in the dog the effects obtained on the blood-pressure and respiration by trikresol seem partly dependent on an increased intraspinal pressure: local applications of 0.3 per cent. trikresol in saline on the medulla of dogs does not give the same quantitative effect on the respiration and blood-pressure as subdural injections; and in monkeys a single injection of trikresol serum following several injections of normal serum exerts usually a greater effect on the blood-pressure than when trikresol serum is injected first.

Tests with serums containing 0.3 per cent. chloroform, 0.3 per cent. ether or no preservative at all, showed that they exerted qualitatively the same effects when injected intraspinally as trikresol serum, but quantitatively the disturbances of respiration and blood-pressure were definitely less. Chloroform serum caused in general a smaller effect on the respiration and blood-pressure than trikresol serum, but the best results were obtained with 0.3 per cent. ether serum and with serum without any preservative, although both still occasionally produced in the dog stoppages of the respiration lasting a minute or two, and a considerable lowering of the blood-pressure. In the monkey, however, normal serum or ether and chloroform serum produced practically only negligible effects on the respiration and blood-pressure.

THE IDEAL ANTISEPTIC

Without discussing the necessity for preservatives in therapeutic serums, it is clear that a volatile antiseptic would be the ideal one to use, for such a preservative could easily be removed by warming the serum container before injection.

The opsonic index of the same antimeningitis serum kept without antiseptics or preserved by 0.3 per cent.

trikresol, 0.3 per cent. chloroform or by 0.3 per cent. ether showed practically the same value after one month, according to experiments carried out by Dr. Martha Wollstein.

The experiments show that dogs in which laminectomy has been performed are much more sensitive to 0.3 per cent. trikresol serum than are monkeys in which intraspinal injection is directly made. The monkey in this as in other respects is more nearly related to man; and in view of the rarity of the accidents mentioned above in man it may be inferred that monkeys react to intraspinal injections in a manner more truly representing the effects in him.

It should be emphasized that respiratory failure is the great danger after trikresol injection in the dog, and that it occurs only rarely in the monkey. In my experiments the drop of blood-pressure even if profound was never fatal in the dog or monkey unless the respiration was permitted to fail. This danger was reduced in two ways: by being prepared to give efficient artificial respiration when necessary, and by replacing the trikresol with a volatile antiseptic like chloroform or ether. It must be pointed out, however, that artificial respiration was apparently necessary in some cases even when serums without any preservatives were injected intraspinally.

APPEARANCE OF NON-COLLOIDAL NINHYDRIN-REACTING SUBSTANCES IN THE URINE

UNDER NORMAL AND PATHOLOGIC CONDITIONS AND DURING PREGNANCY *

F. H. FALLS, M.D.
AND
WILLIAM H. WELKER, Ph.D.
Fellow in Obstetrics and Assistant Professor of Physiologic Chemistry, respectively, in the University of Illinois, College of Medicine
CHICAGO

While we were studying the question of the possible substitution of aluminum hydroxid cream for the parchment diffusion thimbles in the Abderhalden serum diagnosis of pregnancy, there appeared Warfield's paper[1] on the presence of dialyzable ninhydrin-reacting substances in the urine of pregnant women. This led us to turn our attention to a study of the urine under normal and pathologic conditions and during pregnancy.

LITERATURE

Since the publication in 1906 of Pfaundler's[2] work on the determination of amino-acid nitrogen in the urine, there has remained little doubt as to the appearance of appreciable amounts of this class of compounds in normal urine. This work was confirmed a few months later by Krüger and Schmidt,[3] using a different method. These investigators found amino-acid nitrogen to the amount of from 0.325 to 0.45 gm. in from 5 to 6 per cent. of total nitrogen in normal urine.

Embden,[4] and Embden and Reese,[5] on the basis of results obtained by using their modification of the beta-naphthalin-sulphochlorid method, came to the conclusion that as high as 1 gm. of glycocoll may be eliminated daily under normal conditions.

In addition to the glycocoll compound there were found compounds of other amino-acids which Embden and Reese were, however, unable to identify. The weights of the amino-acid compounds isolated in five normal cases were as follows: 1.62, 2.74, 1.48, 1.73, 2.80 gm. daily. These amounts represent 4.32 to 5.10 per cent. of total nitrogen. This, according to the investigators, expresses the minimal amount. Since 1905 many investigations have been carried out on the amount of amino-acid nitrogen eliminated under normal conditions.

Frey[6] found from 0.2 to 0.5 gm. amino-acid nitrogen under normal conditions, Magnus Levy[7] from 2 to 6 per cent. of the total nitrogen, Henriquez[8] 2 per cent. of the total nitrogen on a mixed diet, Masuda,[9] in the case of low protein diet, from 1 to 3 per cent. of total nitrogen, and on high protein diet from 4 to 5 per cent. Joshida[7] found amino-acid nitrogen varying from 0.5 to 2 per cent., and Falk and Saxl[10] from 1.5 to 3 per cent., Siquorelli[11] found 2 per cent. of total nitrogen in normal cases on mixed diet. Galambos and Tausz[12] found from 0.236 to 1.05 gm. amino-acid nitrogen and 1.58 per cent. and 4.35 per cent. of total nitrogen.

It would appear from the evidence presented that amino-acids form an appreciable part of the normal nitrogenous elimination. If ninhydrin reacts with compounds containing the intact amino group in the α, β, etc., position to the intact carboxyl group, then all normal urine should react positively with the reagent, unless the urine contains interfering substances or the content of the amino-acids falls below the limits of delicacy of the reagent.

COLLECTION OF SAMPLES

The urine was obtained fresh and in nearly all cases about four hours after meal-time. The patients suffering from various pathologic conditions were on a liquid or light diet with the exception of the tabes and general paresis patients who were on a general diet. The pregnant women and the normal persons were on a general mixed diet.

METHOD

For the removal of the colloidal substances in the urine we used the aluminum cream according to the method of Marshall and Welker,[13] who showed that this substance can be used for the quantitative removal of colloids from their solutions. Ten c.c. of urine was mixed with an equal volume of aluminum hydroxid cream and the mixture was shaken and filtered. Ten c.c. of the filtrate was treated with 0.2 c.c. of a 1 per

cent. ninhydrin solution and heated on a Chaddock burner for exactly one minute after boiling had begun. The depth of color was observed and noted after the tubes had been standing for half an hour at room temperature. In all the samples containing albumin the filtrate from the aluminum treatment was tested by means of the heat coagulation or Heller's ring test, in order to be certain that sufficient aluminum hydroxid had been used to remove all the albumin. A summary of results is given in Table 1. A complete tabulation of the results will be incorporated in the protocols in the reprint of this paper.

EXPERIMENTS OF COMPARATIVE STRENGTH OF REACTION WITH THE FILTRATES FROM URINE, TREATED WITH ALUMINUM HYDROXID AND THE DIFFUSATES FROM PARCHMENT THIMBLES

A study was made of the comparative strengths of the color reactions with ninhydrin when the methods of diffusion through parchment thimbles and precipitation by aluminum hydroxid were used to remove the colloids. A number of urines which gave strongly positive reactions were compared. The diffusion was carried on in C. S. and S. 579 dialyzing thimbles, which had been previously tested to insure impermeability to albumin and equivalent permeability to non-colloidal substances.

Diffusion time was twenty-one hours at room temperature.

The depth of blue color brought out on boiling 10 c.c. with 2 c.c. of a 1 per cent. of ninhydrin solution was greater in diffusates than in the filtrates from aluminum hydroxid.

These results are shown in Table 2.

A comparative study was made of the strength of the ninhydrin reaction on the urines direct, on the filtrates after treatment with aluminum hydroxid and on the diffusates through collodion bags and parchment thimbles.

Ten urines were studied from cases of acute contagious diseases. The urines were obtained fresh and the reaction with ninhydrin on the urine direct and on the filtrate after treatment with aluminum hydroxid was studied at once. The diffusion through collodion bags and parchment thimbles was allowed to proceed eighteen hours and the diffusates tested with ninhydrin. The results are shown in Table 3.

Contrary to the conclusions of C. E. M. Fischer,[14] that the reaction might just as well be applied to any

1. Probably due to ingested iodid.

albumin-free urine, we find that the reaction is much better brought out after treatment by aluminum hydroxid or dialysis.

CONCLUSIONS

1. The presence of non-colloidal ninhydrin-reacting substances in urine is of no value as a means of diagnosing pregnancy.

2. The reaction may be absent or inhibited in the urine of pregnant women as well as in normal and pathologic urine.

3. In the various urines treated the only difference in the ninhydrin reaction between the diffusates through parchment, and the filtrates from the aluminum treatment were those of intensity of colors, the aluminum filtrates showing a less intense color with ninhydrin.

TABLE 2.—COMPARATIVE STUDY OF THE NINHYDRIN REACTION ON THE DIFFUSATE OF URINE THROUGH PARCHMENT THIMBLES AND THE FILTRATE AFTER TREATMENT BY ALUMINUM HYDROXID CREAM

	Parchment		Aluminum Hydroxid	
	Urinary Pigment	Ninhydrin	Urinary Pigment	Ninhydrin
1	Strong	++?	0	++?
2	Faint	+++++	0	+++
3	Faint	+++	0	++?

9	Faint	++	0	+

4. In the urines reacting positively with ninhydrin the removal of colloidal substances favors the production of the blue color given by this reagent with amino-acids. Such urines before diffusion or treatment with aluminum hydroxid give a color which is not so strong and has more of a reddish cast. This is not the result of the dilution alone.

THE VIABILITY OF THE SPIROCHAETA PALLIDA IN DIFFUSE LIGHT AT ROOM TEMPERATURE*

HANS ZINSSER, M.D.
AND
J. GARDNER HOPKINS, M.D.
NEW YORK

In connection with our work on the *Spirochaeta pallida* it occurred to us that it would be of much hygienic interest to determine how long the spirochete would survive, in diffuse light and at room temperature, under conditions simulating roughly those prevailing when syphilitic discharges are deposited as drops of fluid on hard surfaces, soaked in a cloth, a towel for instance, or dried on glass, as would occur in their deposit on drinking cups, etc.

In order to simulate as nearly as possible the conditions prevailing in discharges, we carried out this experiment with fluid cultures which were contaminated both with cocci and with bacilli in which very large numbers of spirochetes were present. The culture used was one that had been planted in a flask of mixed ascitic fluid and salt solution fourteen days before. This fluid contained rather more spirochetes per drop than we have seen, except in the most profusely positive primary and secondary lesions. In its composition of about half and half ascitic fluid and salt solution it was closely similar to exudates from the body.

The following experiments were made:

Experiment 1.—A series of twelve test-tubes, 20 cm. long, as used in the cultivation of the *Spirochaeta pallida* by Noguchi's method, were sterilized and, into the bottom of each were placed about 3 drops of the mixed culture. These tubes were then exposed, on the middle of a high table in a light laboratory room with southern exposure, in bright diffuse light. The temperature of this room ranged from 22 C. (71.6 F.) at the beginning of the experiment (April 27) to 25 C. (77 F.) at 6 p. m. and 21.5 C. (70.7 F.) at 10 p. m. At the end of varying periods, as indicated in Table 1, a bit of sterile kidney-tissue was placed into each tube, this covered with a mixture of neutral agar and ascitic fluid, the column then sealed with oil and the tube incubated. At the end of thirteen days, dark-field examinations were made and profuse growth found in the tubes marked "positive." The results of the experiment are found in Table 1.

* In this and the following tables + means positive and — negative.

Experiment 2.—In this experiment similar tubes were set up, but the material placed into them consisted of little bits of towel-cloth which had been dipped into the spirochete culture. An ordinary laboratory towel was cut into small squares, sterilized in a dry oven, and these little pieces dipped into the fluid culture until thoroughly soaked. The excess fluid was then shaken off but the cloth not thoroughly dried. Its condition was one of distinct moistness, though not dripping, when placed into the tube. The exposure was carried on just as before, the little bits of towel remaining during the period of exposure in the bottom of the test-tubes. Plants were made as in the previous experiment. The results are shown in Table 2.

EXPERIMENT 3.—In this experiment the culture material was allowed to dry on pieces of broken cover-slips. The sterile cover-slips were dipped into the culture and placed in a Petri dish into the incubator. The first tube was planted immediately, while the slips were still moist. After one hour in the incubator the second slip was planted and close observation showed that this was not yet entirely dry—a slight film of moisture still appeared on it. Before the third planting was made the slips were removed from the incubator and dried in the air. Subsequent plants were made with absolutely dry material.

These simple experiments show that, when kept moist, the *Spirochaeta pallida* can live in diffuse light and at room temperature, under conditions of mixed culture (as occurring in the ordinary contamination of materials from the patient) as long as eleven and one-half hours. From the third experiment it appears that drying kills the organism rapidly. During the period of drying, however, for as long as one hour, the spirochete may remain alive.

We are quite aware that the artificial conditions produced by us do not exactly simulate those prevailing when the material is deposited freshly from the patient on articles freely exposed to the air and not enclosed in test-tubes. As far as the first consideration is concerned, it would seem that organisms deposited fresh from the patient might be even more thoroughly protected than those employed by us, in that they are often contained in mucous discharges which dry but slowly. Such material on a towel hanging in an ordinary privy or bath-room in which there is apt to be a great deal of humidity, may remain moist for a considerable period, although probably not so long as did the pieces of towel enclosed in our test-tubes. As far as the light conditions are concerned, these were probably more severe in our experiments than they would be in the ordinary dark corner in which are located the places where such contamination might take place.

437 West Fifty-Ninth Street.

Primitive Ideas.—The heart, according to Aristotle, was the seat of the soul, and the birthplace of the passions, for it held the natural fire, and in it centered movement, sensation and nourishment.—Elliott, Greek and Roman Medicine.

THE PRACTICAL SIGNIFICANCE OF THE ADRENALS *

R. G. HOSKINS, PH.D.
Associate Professor of Physiology, Northwestern University Medical School
CHICAGO

Although the last word in regard to the functions of the adrenals has by no means been said, enough evidence has accumulated to justify certain conclusions which will probably stand the test for further research.

Perhaps the most significant discovery of recent years is that epinephrin has the remarkable characteristic of going through the body and selectively stimulating the sympathetic nervous system, or, more specifically the terminal "receptive substance" which forms a functional connection between the sympathetic nerve-endings and the tissues.[1] The effect of the drug in any organ depends on whether or not it has a sympathetic innervation. If not, no effect occurs. If sympathetic fibers are present, the effect is stimulation or depression, depending on the function normally mediated by these fibers. Considering that the sympathetic system has a regulatory influence on many vital processes, the body is peculiarly exposed to the influence of the adrenal secretion. Moreover, this secretion acts strongly in remarkably dilute solution. For instance, the presence of 1 gm. in 100,000 liters, or 1 grain in 1,500 gallons of fluid bathing a piece of isolated intestine is sufficient to check its activity.[2] This being true, the adrenals are potentially a very important factor in regulating bodily activity. It thus becomes a very practical question as to when and under what conditions this highly potent substance is discharged into the blood-stream. If this occurs to any considerable extent, the adrenals must be regarded as an important factor in the normal physiologic functioning of the body as well as in nearly every symptom-complex.

The conditions governing adrenal discharge have been under investigation for the last three years in Cannon's laboratory at the Harvard Medical School.[3] Cannon, in studying the activities of the alimentary tract, had noticed that an outburst of emotion — fear or anger — resulted in a checking of peristalsis which persisted some time after all evidence of the emotion had passed. He suspected that this might be due to the presence in the blood of epinephrin secreted as a result of the emotion. Direct research confirmed the fact that augmented adrenal discharge does occur as a result of strong emotion. If emotion causes such an effect, pain, the most common cause of emotion, might be expected also to cause adrenal discharge. This was found to be the case. Asphyxia has been shown by several investigators to be equally effective.

Since this adrenal discharge is purely reflex, and since reflexes are usually of direct benefit to the individual, the question arises, Of what use is this arrangement? McDougal has suggested that emotions are the mental representation of bodily activities: anger represents combat, fear represents flight. In case combat results, pain is at once experienced. Either flight or combat causes partial asphyxia — at least until the body has had time to adjust to the conditions. The adrenal discharge might be supposed, therefore, to aid in some way in strenuous muscular activity; that is, to integrate the body for muscular response to the stressful condition which caused the discharge.

* Read before the Illinois State Medical Society, Decatur, 1914.

[1] Elliott: Jour. Physiol., 1905, xxxii, 401.

[2] Hoskins: Am. Jour. Physiol., 1912, xxix, 363.

[3] For an excellent summary of the research see Cannon: Am. Jour. Physiol., 1914, xxxiii, 356.

As a matter of fact, the injection of epinephrin does have a number of effects that aid in violent muscular activity. A quiescence of the whole digestive system results and the blood is shifted from the splanchnic circulation to the active muscles, the nervous and respiratory organs. The circulation in these organs is further increased by a rise of blood-pressure resulting from vasoconstriction of the splanchnic area and often of the skin, as well as by augmented cardiac discharge. A discharge of dextrose occurs, leading to hyperglycemia, whereby the laboring muscles supposedly obtain a better supply of energy material. This hyperglycemia has been observed as a direct result of strong emotion as well as of artificially augmented epinephrin. The well-known bronchodilator effect of epinephrin is of obvious utility in aiding free breathing whereby the oxygen necessary to violent activity is secured. Most striking of all, however, the laboring muscle itself is directly benefited. Cannon and Nice[4] observed that after the injection of epinephrin or stimulation of the splanchnic nerves to cause adrenal discharge, the efficiency of a fatigued muscle is improved, sometimes 100 per cent. Gruber[5] has found that recovery from fatigue is greatly hastened by the injection of epinephrin. The explanation of this fact is not definitely known, but a hint is offered by Evans and Ogawa's[6] observation that in the heart at least the assimilation of oxygen is increased by epinephrin. Cannon, Gray and Mendenhall[7] have discovered another remarkable fact which is of further use to the individual in case the stressful condition results in bodily injury: epinephrin lessens the coagulation time of the blood. This is true, however, only within physiologic limits for such quantities as can be obtained by stimulating the splanchnic nerves. In case greater quantities are employed, the coagulation is interfered with. With proper regard to this fact, epinephrin should come into frequent clinical use in combating hemorrhage. Cannon suggests that the pains of labor are of direct use to the mother in causing adrenal discharge and thereby protecting her from post-partum hemorrhage.

Some of these facts are of direct clinical importance. The emotional instability of the neurasthenic and continual worry or fear in the normal person probably subject them to frequent adrenal stimulation to the detriment of their vegetative activities, particularly of digestion. The dangerous influence of emotional stress in persons with high blood-pressure or hard arteries is to be ascribed partly to an adrenal factor. Similarly a diabetic is to be protected from conditions causing adrenal discharge because of the tendency of epinephrin to aggravate hyperglycemia.

The fact that injecting epinephrin is exactly equivalent to a general stimulation of the sympathetic system and the common supposition that an animal after removal of its adrenals dies in a condition of vasomotor failure, at least strongly suggest that the paramount function of these glands is to maintain tonus in the sympathetic system. This hypothesis may be designated the "tonus theory." It supposes that the adrenals constantly pour into the blood-stream epinephrin in sufficient amount to keep the sympathetic system in a condition of partial stimulation.

A number of facts may be mentioned, however, which are not consistent with the theory. In the first place, the adrenal glands seem to have at best but a very limited capacity.[8] The doses of the drug that are given in pharmacologic demonstrations are probably greatly out of proportion to any amount which the glands can secrete. If small quantities of the drug are given, the most prominent effect is a vascular depression.[9] If during periods of quiet existence the glands have any effect, it is likely that it is a depression of the sympathetic system.

We have excellent reason, however, to think that ordinarily the sympathetic system is not at all under epinephrin influence. It is easy to place ligatures in such a way that they can be drawn tight from outside the body and shut off the adrenal circulation without affecting any other important structures. While a blood-pressure record is being taken on an animal so prepared, the adrenals can be isolated quickly. Whatever influence they may have been having is immediately removed. If they have been keeping up sympathetic tonus, a fall of blood-pressure should immediately occur; but the effect of so isolating the glands is nil.[10]

Another fact may be mentioned: If epinephrin be injected at a very small but gradually increasing rate, no effect at all is at first to be seen. Then various changes occur. One of the earliest is a depression of peristalsis. This is noted before any tonic influence on the circulation appears.[11] It is obvious that any mechanism which could keep up sympathetic tonus only at the expense of intestinal paralysis would be of little use. This fact, as suggested by O'Connor, has an important clinical bearing. There have been numerous attempts to incriminate the adrenals in cases of high blood-pressure; but any degree of epinephrin secretion sufficient to cause continual hypertension is out of the question and the explanation, whatever it be, is to be sought elsewhere. This conclusion is strengthened by the observation that epinephrin glycosuria is also produced before the blood-pressure is raised.[12]

Attractive as the tonus theory is, such data render it no longer tenable. But the fact remains that adrenal extirpation is fatal and the final symptoms are supposed to include a primary failure of functions under sympathetic control, notably of blood-pressure. Elliott[13] has offered the suggestion that adrenal deficiency results in the loss, not necessarily, of any tonic stimulant, but of a substance necessary for the maintenance of sympathetic irritability; that is, that epinephrin is of importance in the transmission of impulses through the myoneural "receptive substance." There is nothing in the available evidence which disproves the suggestion.

Another hypothesis equally capable of explaining the results of adrenal extirpation has been made, namely, that the adrenals in some way directly promote the metabolism of the muscular tissues.[14] In the absence of the glands, myasthenia develops. This asthenia, if it included the circulatory apparatus, would lead to low blood-pressure. The negative phase of the hypothesis is equally tenable, that is, that the adrenals destroy some substance which interferes with muscular metabolism. In this form the suggestion is an old one.

Elliott's suggestion is amenable to experimental investigation. If adrenal destruction results in an interference with sympathetic functioning, the fact should be easily demonstrable. Accordingly, a series of experiments has recently been carried out in our laboratory at Northwestern in the hope of determining the matter.[15] We used the vasomotor system as a criterion of the condition of the sympathetic system as a whole. The method, in brief, was to isolate the adrenal glands and then, after the animal began to react to adrenal deficiency, to test the functional condition of various parts of the vasomotor apparatus. The injection of pituitary extract, which acts on the vascular musculature itself, showed that this tissue was not impaired. Similarly epinephrin showed that the myoneural receptive substance reacted normally. The condition of the sympathetic cells proper was determined by injecting nicotin, which selectively stimulates these. At a time when the animal was almost moribund, the reaction to nicotin was not only unimpaired, but often even somewhat augmented. Finally, stimulation of afferent nerves produced an undiminished pressor effect. It was concluded, therefore, that the vasomotor system as such is not influenced by adrenal destruction. Parenthetically, attention may be called at this point to a fallacy in the clinical use of epinephrin as a test of *sympathicotonie* in exophthalmic goiter and other conditions. Epinephrin has little or no influence on the sympathetic system proper. Its action is restricted to peripheral structures, that is, to the "receptive substance." An exaggerated reaction to epinephrin does not at all indicate, as is popularly supposed sympathetic irritability. Indeed, as Elliott has shown, it is a characteristic sign of sympathetic degeneration. We have had numerous opportunities to observe that there is no necessary parallelism between true sympathetic irritability and augmented reaction to epinephrin. The use of epinephrin in this connection, therefore, is absurd. Nicotin would be a much more logical agent.

In connection with the experiments just mentioned we were able to confirm the observation that low blood-pressure does result from destruction of the adrenals, but that there develops a marked weakness of the heart which is alone enough to account for the hypotension. Experimental adrenal deficiency, therefore, is seen to involve selectively the cross-striated muscle, cardiac as well as skeletal. The same is probably true of Addison's disease.

In view of the fact that the adrenals consist of two distinct parts the question arises, Which of these is concerned in such experiments? The results of adrenal deficiency are commonly ascribed to loss of the medullary portion from which epinephrin is secreted. Without attempting any exhaustive discussion of the question, some of the more pertinent evidence may be mentioned. If *epinephrin deficiency* were the significant factor it could easily be compensated for by the continuous injection of the drug; but observers are agreed that this procedure is futile.[16] Death at best is but slightly delayed. Biedl[17] has concluded from extirpation experiments in animals in which the two parts of the gland are separate that it is the loss of cortical substance which causes asthenia. Various observers have seen animals kept alive after adrenal extirpation by the hypertrophy of fragments left behind in the operation; but in such cases it is the cortical tissue that hypertrophies.[17] Moreover, as Loewy[18] has recently reported, the characteristic syndrome of Addison's disease may develop in patients in whom the cortical tissue alone is deficient. Weed[19] of Johns Hopkins has recently reported a crucial experiment on the point. By successive operations an animal was deprived of all its adrenal tissue except one small fragment. Ligatures were then so placed that the circulation of the cortical part was destroyed, but the medullary part left unaltered. The animal promptly died.

On the whole, it seems most likely that the characteristic asthenia of adrenal deficiency is due to the loss of cortical tissue, whereas the medullary part has as its chief function the furnishing of a special stimulant to enable the body to cope with emergencies.

In summary we may say that the available evidence indicates that the adrenals secrete a substance, epinephrin, of remarkable potency. This substance selectively affects the tissues having sympathetic nervous control, thereby affecting many vital functions. Adrenal discharge occurs when the individual is subject to stress, as strong emotions, pain or asphyxia. The discharge integrates the body for muscular response: (*a*) by shifting the blood from the vegetative to the motor, nervous and respiratory organs; (*b*) by increasing blood-pressure; (*c*) by causing discharge of dextrose into the blood for use of the laboring muscles; (*d*) by dilating the bronchioles, permitting freer breathing, and (*e*) by reducing fatigue. It also hastens the coagulation time of the blood; *a*, *b* and *c* are of direct clinical importance.

During quiet existence the epinephrin secretion, if occurring at all, is below the threshold necessary to stimulate the sympathetic system. Sympathetic activity *per se* is not impaired by adrenal extirpation.

Adrenal destruction results in fatal asthenia of the skeletal and cardiac muscle. This is probably due to loss of adrenal cortex, not epinephrin-secreting tissue. Addison's disease is probably due, therefore, to functional failure of the adrenal cortex.

Qualities of a Surgeon.—Celsus, who lived during the reign of Augustus, described the qualities which should distinguish a surgeon as follows: He should not be old, his hand should be firm and steady, and he should be able to use his left hand equally with his right; his sight should be clear, and his mind calm and courageous, so that he need not hurry during an operation and cut less than required.

PRACTICAL STUDY OF GOAT'S MILK IN INFANT FEEDING AS COMPARED TO COW'S MILK[*]

DeWITT H. SHERMAN, M.D.
AND
HARRY R. LOHNES, M.D.
BUFFALO

This study was made to learn, if possible, why goat's milk agrees better with some infants than cow's milk. The babies were selected at random from the inmates of St. Mary's Infant Asylum and Maternity Hospital. The goat's milk averaged from 0.5 to 1.5 per cent. richer in fats than the cow's milk used in this institution. Nevertheless, in making our modifications of the two milks the same amount of each milk was used in the stock formulas. Consequently the caloric value of the goat's milk modifications was greater than that of the cow's milk.

We shall present our data under various headings.

RESULTS OF GASTRIC ANALYSES

All test-meals were withdrawn one hour from the middle of the feeding. The amount recovered averaged, in fourteen cases, nearly twice as much of cow's milk formulas as goat's milk, the accurate ratio being 41:27 c.c. This points to the slower digestion of cow's milk.

The curds of the goat's milk formulas were smaller and more flocculent, corresponding to the appearance in test-tube digestion.

The analyses in fifteen cases with goat's milk, and in fourteen cases, in the same children, with cow's milk, gave the averages shown in Table 1.

TABLE 1.—AVERAGES OF ANALYSES WITH GOAT'S MILK AND COW'S MILK

	Goat's Milk	Cow's Milk
Free hydrochloric acid	Once	None
Combined hydrochloric acid	22.00	28.20
Acid salts	5.53	5.30
Total acidity	28.4	33.50

In a previous paper[1] we calculated the average gastric analysis on (*a*) barley-water and (*b*) proprietary foods containing some proteins, fat, sugar and carbohydrates, but no milk. For convenience of comparison, we give in Table 2 the averages of these and also of modified goat's and cow's milk, as shown in Table 1. This table indicates the greater stimulating effect on the stomach of cow's milk than goat's milk, the greater stimulating effect of both than of the proprietary foods made without milk, and finally the greater stimulating effect of all three than of barley-water.

In some vomiting cases Table 2 gives definite information as to the causal factor of this condition in these four kinds of foods (*a*) through direct gastric stimulation, (*b*) because of the size and density of curds and (*c*) because of slower digestion.

TABLE 2.—COMPARISON OF ANALYSES

	Free Hydrochloric Acid	Combined Hydrochloric Acid	Acid Salts	Total Acidity
Barley water	2.10	5.60	....	9.00
Proprietary foods containing some proteins, fat, sugar and carbohydrates, but no milk	None	10.50	....	17.40
Goat's milk with rice water and 2 per cent. cane-sugar solution	None	22.00	5.53	28.40
Cow's milk with similar and other modifications	None	28.20	5.30	33.50

CLINICAL OBSERVATIONS

As regards absorption and gain in weight our statistics are indefinite for three reasons: First, the babies being institution babies were apt to gain slowly; second, owing to an epidemic of streptococcus infection, which had swept through the infant's ward, causing gastro-intestinal disturbances so serious that about one-fifth of the babies died, the digestion of those who did recover, was more or less impaired; and third, because a certain number, who were doing well, were removed from the institution through adoption before our experiments were finished.

Of the number tested, sixteen cases in all, on similar formulas, twelve gained more rapidly on cow's milk modifications, and four on goat's milk. The gain of the former group was in the ratio of 3:1. The gain of the latter group was in the ratio of 9:1. Consequently those who did gain on goat's milk gained more rapidly than on cow's milk, but fewer gained on goat's milk.

In infantile atrophy and inanition, three cases, goat's milk was no more suitable than any other food.

Taste of Goat's Milk.—At first the babies did not finish all their bottles, not liking the flavor of the food as well as of cow's milk. This surprised us, because there seemed to us to be no unusual taste, as is usually supposed to be the case. If the milk is clean, we think the strong taste so common in Switzerland is unnecessary, and believe that the taste, as well as odor, is due to lack of udder cleanliness or possibly the type or food of the goat. In the goat's milk taken from three sources in this state — Geneva, East Aurora and Buffalo — we have never found the strong taste or odor commonly supposed to be characteristic of goat's milk.

Fats.—In goat's milk the fat averaged from 0.5 to 1.5 per cent. higher than in cow's milk. The more thorough emulsification of the fat in goat's milk, possibly the finer fat globules, prevents the separation of the cream on standing, as occurs in cow's milk. This fact may be an element in reducing the tendency to regurgitation in goat's milk as compared to cow's milk, and further, may be a very important factor in lessening the liability to sour vomiting, due to fatty acid fermentation, so common in high fat mixtures of cow's milk.

Strength of Formulas.—The babies, as a whole, tolerated equally well similar amounts of goat's or cow's milk with the same diluents, but as the goat's milk contained higher fat than cow's milk, they actually received more fat per feeding, and hence higher caloric value. It is consequently strange that more babies gained, as stated above, on cow's milk than on goat's milk modifications.

In our formulas, fat rarely averaged over 2.25 per cent. in goat's milk, and was a little less than 2 per cent. in cow's milk.

Stools.—On goat's milk the stools were as a rule smaller and of a more vivid yellow.

Age.—This did not influence materially the ratio of gain on goat's versus cow's milk, but the younger the baby, the more the evidence pointed toward a greater gain on goat's milk.

Vomiting.—Of twenty-four children receiving both goat's and cow's milk formulas, five vomited goat's milk some, and none cow's milk. The explanation may be the slightly lower fat percentage in the cow's milk formulas. On the other hand, in certain cases goat's milk is often tolerated in similar amounts because of the fact that there is less gastric stimulation, that is, smaller, lighter curds.

[*] Read before the Pediatric Section of the New York State Medical Society at Rochester, April, 1913.

[1] Sherman, DeWitt H.: Gastric Analysis in Infants, The Journal A. M. A., May 7, 1910, p. 1514.

After getting accustomed to goat's milk more children seemed hungry, and cried more at night than when taking cow's milk.

The type of modification commonest used was similar amounts of goat's milk or cow's milk diluted with rice-water and 2 per cent. cane-sugar.

We are very much indebted to Dr. W. H. Jordan, director of the New York State Agricultural Experiment Station, for sending us for six weeks 16 quarts a day of goat's milk in the best of condition. We are also indebted to Sister Frances and Sister Clare at St. Mary's Infant Asylum and Maternity Hospital for their assistance and cooperation in our work.

THE HEMAUROCHROME REACTION

HERBERT S. CARTER, M.D.
WITH
SELMA GRANAT AND SARA DUPONT
NEW YORK

In June, 1913, T. G. Davis[1] of Los Angeles called attention to a substance which he called "hemaurochrome,"[2] which he found present in the urine in certain diseases. This he concluded was derived from hematin and occurred as a result of blood destruction in such diseases as carcinoma and sarcoma, in a series of cases of which he never failed to find the reaction. He also found it in malaria, anemias due to intestinal parasites, essential anemia due to near malignant disease of the lymph-glands and ductless glands, especially in hyperthyroidism in splenic, myelogenous and pernicious anemias.

In the cases here tabulated the reactions were divided into (1) negative, (2) faint (pinkish color), (3) moderate and (4) marked reaction. As the real hemaurochrome gives a rather deep pink, only the moderate and marked reactions are considered as positive.

During the past eight months the urine of about 350 cases of all sorts from the medical and surgical services of the Presbyterian Hospital, New York, have been tested for this reaction and the results are here tabulated.

The greatest interest at first naturally centered about the cases of new growth of all kinds, as it was hoped that a valuable method of differential diagnosis between malignant and benign tumors might be proved, Davis having reported such favorable results. There were seventeen cases of carcinoma and two of sarcoma; of the nineteen cases, ten were proved malignant by necropsy or operation, and in nine the diagnosis was practically certain from the clinical findings. Of these nineteen cases, in four, of the malignancy of which there was absolute certainty, the reaction was missing or inconclusive. Four cases of those clinically malignant also failed to show the reaction. Six of the certainly malignant cases gave positive reactions and five of those clinically malignant did also. To put it in another way, four positively malignant and four probably malignant cases failed to give the reaction, and six positively malignant and five probably malignant cases gave the reaction.

The only reasonable conclusion one can reach in regard to these cases showing a new growth is that if the reaction is moderately or strongly positive, malignancy can be suspected. Negative findings, however, do not by any means rule out the diagnosis, so that the usefulness of this test is decidedly limited and Davis' contention is not borne out.

Of the three cases of malaria, two showed a marked reaction, and it seems likely that this would be regularly so. Of the anemias, three cases of splenic anemia failed to show a reaction. In two cases of pernicious anemia, one failed, and the other gave a marked reaction. Of the simple and secondary anemias, the percentage of hemoglobin seemed to have little influence on the presence or absence of the reaction; the complicating conditions apparently determined it. In classifying the cases by diagnosis, however, we were struck with the frequency with which we met a positive reaction in gastro-intestinal ulceration, particularly in cases diagnosed as peptic ulcer, whether gastric or duodenal. Of these there were fifteen cases of fair certainty, most of them proved by operation, necropsy or a typical history with hemorrhage. Of these, three gave no reaction (one was made one month after the operation) while twelve gave good reactions. Two of these cases gave the reaction during the early part of the series when we were chiefly concerned with the diagnosis of cancer, operations, however, proving them both simple ulcerations (in one, sections were cut from the excised ulcer). In five cases diagnosed as simple hyperchlorhydria without discoverable lesion, two cases gave a good reaction, and the subsequent history of both makes it most probable that they were really cases of ulcer.

It was hoped that in this large percentage of positive reactions in ulcer cases we might have found a helpful diagnostic point in the often difficult task of differentiating ulcer from chronic appendicitis or gall-bladder disease. There were six cases of chronic appendicitis examined, two of which gave positive reactions; both these cases were unproved; both patients complained of epigastric pain and were in the doubtful class.

Four cases of gall-bladder disease were examined, all failing to show a reaction, so that the presence of a good reaction in these doubtful cases is at least highly suggestive of ulcer.

One investigator thought that the presence of considerable amounts of indican in the urine accounted for many reactions, but in this series this was distinctly not the case, as of the fourteen cases that gave a marked reaction for indican, none showed a positive hemaurochrome. The presence of indolacetic acid had no influence on the reaction. There were twenty-four normal cases examined, none of them giving a reaction. There were numerous surprises in the following cases, however, in that some cases gave reactions entirely unexpectedly, none of them belonging to any of the classes in which Davis had found reactions:

Nervous dyspepsia, 2 positive. Both cases suspicious of ulcer, not proved.

---

[1] Davis, T. G.: Am. Jour. Med. Sc., June, 1913, p. 857.

[2] Hemaurochrome test: To 100 c.c. of urine add 10 c.c. hydrochloric acid. Heat slowly until it boils, remove and when cool add 30 c.c. ether. Agitate carefully. After twelve hours pour ether into white porcelain dish and evaporate. If the reaction is positive there is a deep pink color left in the dish.

Chronic cardiac decompensation, 21 negative, 3 positive.
Jaundice, 1 positive.
Gastroptosis, 1 positive.
Atonic constipation, 4 negative.
Intestinal fistula, 3 negative.
Typhoid fever, 9 negative, 4 positive (day of disease not a factor).
Arthritis deformans, 2 positive.
Diabetes mellitus, 5 negative, 2 positive.
Cerebral hemorrhage, 1 positive.
Hematuria, 1 positive.
Gonorrheal arthritis, 1 positive.
Aneurysm of arch, 1 positive.
Syphilis (or Wassermann), 19 negative, 4 positive.
Bronchitis, 10 negative, 1 positive (probably also malarial).
Pneumonia, 8 negative, 1 positive.
Neuritis, 1 negative, 3 positive.
Periostitis, 1 positive.
Dementia paralytica, 1 negative, 1 positive.
Chronic nephritis, 9 negative, 3 positive.
Septicemia, 1 positive.
Myositis, 1 negative, 2 positive.
Not diagnosed, 3 negative, 4 positive.
Esophageal stenosis, 1 negative, 1 positive.
Chlorosis, 16 negative, 15 positive.

One or more cases in the following conditions were examined, none of them showing a reaction: pleurisy, exophthalmic goiter, fatty liver, enterocolitis, acute poliomyelitis, vomiting of pregnancy, polycythemia, secondary anemia, ulcer of the leg, lipoma, enteroptosis, endometritis, uterine fibroids, acute appendicitis, acute parenchymatous nephritis, acute articular rheumatism, neurasthenia, acute leukemia, general arteriosclerosis, constipation, gastritis, tuberculosis, pyelitis, hydronephrosis, cholelithiasis, hysteria, scarlet fever and senility.

In reviewing these findings it will be seen that this reaction of hemaurochrome in the urine is far too frequently found in a wide variety of diseases to be of any specific importance. Indeed, one hesitates to attach any real importance to its presence in a case of suspected cancer or of gastric ulcer when we should like certain help in diagnosis, for the cases may be free of these diseases but still give positive reactions from some other and apparently trifling cause.

It may be said, however, that at least 50 per cent. of cancer cases give a positive reaction as well as a preponderating number of cases of peptic ulcer. In the latter condition especially it would seem worth while making the test in a very large number of cases, that sufficient operative or necropsy data might be obtained to establish its actual incidence. At present all one can say is that a positive reaction in cases presenting symptoms of peptic ulcer makes that diagnosis probable, particularly in contradistinction to a possible gall-bladder irritation or chronic appendicitis, and it may prove to be a test of greater negative than positive value.

66 West Fifty-Fifth Street.

The Speed of Progress.—Primitive views still prevail everywhere of man's relation to the world and to the uncharted region about him. So recent is the control of the forces of nature that even in the most civilized countries man has not yet adjusted himself to the new conditions, and stands, only half awake, rubbing his eyes, outside of Eden. Still in the thaumaturgic state of mental development, 99 per cent. of our fellow creatures, when in trouble, sorrow or sickness trust to charms, incantations and to the saints. —Osler: Specialism in the General Hospital.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLE HAS BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. ITS ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES."

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

ELECTRARGOL.—Electrargol is a colloidal solution of silver containing a small percentage of sodium arabate. It contains silver equivalent to 0.25 per cent. metallic silver (Ag).

Actions and Uses.—Electrargol is claimed to be antiseptic and germicidal and non-irritating even when injected hypodermically or intravenously.

It is claimed to be useful in febrile diseases, even those which are not of a septic character. It is also said to be useful when applied locally in inflammatory conditions, and it has been used in surgical cases.

Dosage.—Subcutaneously, intramuscularly or intravenously it is used in doses of from 5 to 25 Cc. after being made isotonic by the addition of sodium chlorid solution.

Manufactured by Comar & Cie, Paris. No U. S. patent.

Electrargol for Injection.—Supplied in the form of ampules, each containing electrargol 5.0 Cc. (75 minims) in the non-isotonized condition. The package contains a solution with directions for the extemporaneous isotonization of the preparation.

Electrargol for Surgical Use.—Supplied in bottles each containing electrargol 50 Cc. (1.7 fluidounces) isotonized by sodium sulphate.

Electrargol is prepared by passing an electric current in the form of an arc between two silver electrodes in distilled water. It is made stable by the addition of sodium arabate, which is prepared by acting on acacia (gum arabic) with hydrochloric acid, precipitating the resulting arabic acid with alcohol and neutralizing the arabic acid with sodium carbonate.

Electrargol is an odorless, tasteless liquid, appearing transparent and reddish brown by transmitted light and opaque and gray by reflected light. The addition of potassium cyanide solution or of strong nitric acid yields a colorless transparent solution. The nitric acid solution yields a white turbidity on the addition of chlorids.

Therapeutics

SOME OVERLOOKED CAUSES OF CHRONIC ILLNESS

(Concluded from page 1725)

EYE-STRAIN

In spite of frequent reference to this subject, only a small proportion of physicians consider it important, though it is generally recognized that headaches are frequently due to eye-strain. About 90 per cent. of all recurrent headaches are due to conditions in the eyes. Of course, only a certain proportion of such headaches will be cured by correcting the optical defects; in fact, some patients will have eye aches in spite of corrective glasses. There may be congenital or acquired muscle weaknesses that are impossible to cure; that is, an eye that will meet one test at one time will give an entirely different test on other days. Such patients are the greatest chronic sufferers that we have; they are always subject to actual headache or disturbing reflexes, and still they do not die from it.

As just stated, actual headaches, especially frontal or in the eyes, are recognized by most physicians as due to eye defects, and such patients are sent to oculists. It is not recognized, however, that some patients who have no headache still may have reflexes from eye-strain. These reflexes are largely gastric, and vary from flatulence, hyperacidity and delayed digestion to dizziness, nausea and vomiting. These patients may have cold hands and feet, shiverings, feelings of faintness and often have palpitation attacks and irregular hearts. They may even have cardiac pains.

There are patients who have been treated for neurasthenia for months, or even years; patients who have had their stomachs washed out daily for a time, or weekly for a longer time for supposed stomach trouble; patients who have been treated for heart-disease, for hyperacidity, for gastric ulcer, for intestinal indigestion, etc., who have been cured by the proper glasses; if there is any astigmatism, keeping the glasses straight is especially important.

The following items are essential to the best results in cases of eye-strain:

1. The oculist must carefully test each eye and decide with care on the glasses needed.
2. The best optician possible should be selected to fill the prescription, and he should give careful attention to the kind of frame, the length of the posts and the closeness to the eye at which the glasses should sit, etc. In fact, the adjustment is all-important.
3. The patient should return to the oculist to ascertain if the glasses are correct and correctly adjusted.

The oculist is no more infallible than are the rest of us, and we should urge a patient to continue with one oculist until it is proved that he does not succeed in correcting the defect in the patient's eyes. Then the patient with defective eyes has a right to seek consultation just as if the disturbance were in any other part of the patient's anatomy. Also, it must be impressed on an astigmatic patient that a correct glass must always be in the proper position; the moment that that glass is deflected, it does not cure the ocular error. Consequently, frequent adjustment by the optician should be advised and urged. Also, the patient should understand that his eyes will change, and consequently the glasses will need to be changed, the length of time varying from six months to several years.

In making a careful examination of a patient who comes for varying conditions (and it is astonishing how many of these patients will come saying they have heart-trouble or stomach-trouble, and the whole emphasis is put on some other part of the body than the eyes) we should first exclude as well as we can every possible organic condition that could cause the disturbances present. The examination of the urine should never be forgotten. Specific questions aiming toward the elaboration of the part the eyes play in the disturbances are as follows:

1. Is there headache?
2. Is there nausea, and what is the relationship of the nausea or vomiting to the headache? Does the headache always precede the vomiting? We shall find that the "bilious attacks" are generally headache attacks. Also, we shall find, when the stomach is not at fault, that as soon as the headache ceases the patient has a good appetite for his next meal. No inflamed stomach can be bad one day and all right the next.
3. What is the periodicity of these headaches, or attacks of nausea or vomiting, or indigestions, or heart-pains? This means not only the frequency, but also the relationship to activity, which will be mentioned later.
4. What is the duration of the disturbance, whatever it is?
5. At what age did these disturbances begin? We shall often find that they go back to school-life.
6. Does the patient like a dark room?
7. When attempting to read, study or write, does he become unexpectedly drowsy?
8. What is the effect of diet? We often ascertain that a patient has omitted from his diet first one article of food and then another, until his diet is down almost to a starvation one, to no purpose; the stomach upset is still repeated.
9. What is the relation of the headaches or stomach or heart reflexes to reading, to work, to theater-going, to card-playing, to the watching of a parade, to visiting the stores and shops, to riding in the cars and to going to the "movies"? All of this will progressively inform us, and will gradually make an impression on the patient. Still we have said nothing about the eyes; we have simply, by our questions, elicited facts. We will find that such a patient often cannot remain throughout a theater performance, or even through a church service. He also gets nervous if he rides in trolley cars; he has ceased to play cards; has gradually stopped reading, and has even become melancholic.

After such questioning, your patient will soon say to you, "Why, Doctor, is it my eyes?" And yet you have not said a word about eyes.

The presbyopic headache is more likely to be in the morning, and may be occipital. Such a headache may be due to high blood-pressure, to insufficient action of the kidneys or to the absorption of some substance produced by intestinal indigestion. A frequent cause of such headaches, however, is presbyopia.

Before leaving this subject, let it be urged that when pain exists anywhere in the head, with functional stomach and heart disturbances, after excluding all other causes by careful examination, the patient's eyes should be studied.

DISTURBANCES OF THE PARATHYROIDS

We do not yet know a great deal concerning the activity of the parathyroid secretion, but it has been shown that these glands are necessary for life, that convulsions occur if all of them are removed, and that the feeding of parathyroid or the administration of calcium will prevent these convulsions and save life. They may be abnormally secreting in certain forms of epilepsy; they may not be doing proper work in many forms of convulsions. Some forms of tetany are quite probably due to a subsecretion of these glands, and the feeding of parathyroid, or the administration of calcium is beneficial. Subthyroid secretion and subparathyroid secretion may be the cause of some forms of puerperal convulsions. It may always be wise to give a pregnant woman, during the last months of pregnancy, medicinal doses of calcium. She needs it not only for the growth of her child, but also to preserve her own teeth and to prevent softening of her own bones, to say nothing, perhaps, of combating the intoxication that may be caused by an insufficient parathyroid secretion.

The relationship of hypersecretion of the parathyroids to certain nervous diseases has not yet been shown, although such a study presents many possibilities of clinical and therapeutic interest.

THE "DAY OF REST" AND HUMAN EFFICIENCY

The refreshing influence of the weekly recurring "day of rest" on a person subjected to the strenuous routine of a busy life is a feature which he himself can duly appreciate in terms of his "feelings" and "spirits." If it is desired to demonstrate the need of such relaxation and the benefits derived therefrom in some objective way, a method is not easily forthcoming. The problem is one which, in its broadest aspects, has a far-reaching importance in every community. The efficiency of the working man, the desirable length of the working-day, the interjection of pauses for rest in the schedule of labor for persons of different ages and stations in life — questions of this sort are constantly arising for solution by some plan which excludes purely subjective impressions and permits some more scientific basis for a tenable judgment in the matter. Not only in the field of manual labor, but also in innumerable other walks of life, in the case of the schoolchild, the office-boy, the factory-girl, the banker and the merchant, efficiency is the key-note of the times. Fatigue is the enemy of efficiency; and to detect and compensate for or overcome it, is the duty of those concerned with the promotion of human welfare.

In view of this it is of more than passing interest, from the standpoint of both public and personal hygiene, to ascertain suitable methods of approach to the problem of fatigue and the lessons which it discloses. Dr. Martin[1] and some of his associates in the Laboratory of Physiology at the Harvard Medical School have devised a satisfactory procedure for estimating variations in electrocutaneous sensibility in human beings. With the onset of general fatigue a progressive rise occurs in the value of the threshold stimulus. This, in turn, signifies a progressive lowering of sensitiveness, and, according to the view of Grabfield and Martin, a diminishing tone of the nervous mechanism as a whole. The Harvard physiologists have made a long series of experiments on first-year medical students in good health who were following a regular routine of school work during six days of each week. The routine was interrupted weekly by the Sunday recess, an interval occupied variously by the students, but in no case in precisely the manner of the week days. The daily observations made on these persons during several weeks show that at the beginning of the week the irritability tends to be high, that from then until the end of the week there is a fairly continuous decline in irritability, as judged by the sensory threshold, and that following the interruption of the routine by the intervention of Sunday, the irritability returns to the original high point.

The decline in irritability is interpreted as a cumulative result of general fatigue incident to routine. What is even more significant, however, is the added fact that a pronounced break in the routine — such as the "day of rest" occasions — may bring about a *return of sensitiveness to a high point or, in other* words, it restores the nervous tone. Studies continued in this direction should lead to some useful conclusions regarding the optimum of work, with respect to both its duration and type, that should determine the conditions under which the organism of man may be maintained without depletion.

THE PRESENCE OF DIPHTHERIA ANTITOXIN IN THE BLOOD OF NORMAL PERSONS

It has been known for some time that diphtheria antitoxin is present in the blood of at least some persons who, so far as known, never have had diphtheria. It is believed that the antitoxin may be transmitted to the child from the mother; it is present in the blood of about 80 per cent. of the new-born, but it soon begins to fade away.

Recently a method has been devised by Römer which makes it possible to titrate accurately the amount of antitoxin in the blood. Briefly, the method consists in the intracutaneous injection in guinea-pigs of a minute quantity of diphtheria toxin and the serum to be tested for antitoxin. If no necrosis results, the toxin has been completely neutralized by antitoxin in the serum. By this method, which permits of accurate quantitative measurement, Otto[1] has tested the serum of a number of persons under different conditions, some being in close contact with diphtheria patients, others not. It was found that there was more than one one-hundredth of a unit of antitoxin in each cubic centimeter of the blood of those who, without having been sick, had been in close contact with cases of diphtheria; others usually had much less. Of six fresh nurses who had less than one one-hundredth of a unit per cubic centimeter of blood, two suffered from diphtheria. These observations are significant because they indicate that this amount of antitoxin in the blood — one one-hundredth of a unit per cubic centimeter — probably suffices to protect against diphtheria. Indeed, Behring is said to have previously expressed his belief in the truth of this theory, and the object of his new diphtheria vaccine is to induce the production of at least that much antitoxin by the body itself. Older persons who have not had diphtheria may carry antitoxin in the blood in comparatively large quantities; nevertheless, the production of the antitoxin must be attributed to effects of invasion of diphtheria bacilli. In other words, the condition is one of active immunity due to infections of such mild character as to escape notice. Undoubtedly physicians and seasoned nurses who are freely exposed to diphtheria and yet rarely contract the disease owe their safety to an active immunity, the result of repeated contact with the bacilli. Otto found that diphtheria carriers, both those who had had the disease and those who had not, contained more antitoxin in their blood than patients who had just recovered from an attack. This shows that the mere presence of bacilli in the throat is sufficient to stimulate the production of antitoxin on which the immunity of the carrier himself would seem to depend.

[1] Martin, E. G., Withington, and Putnam, J. J., Jr.: Variations in the Sensory Threshold for Faradic Stimulation in Normal Human Subjects, III, The Influence of General Fatigue, Am. Jour. Physiol., 1914, xxxiv, 97. Grabfield and Martin: Ibid., 1913, xxxi, 308.

[1] Otto, R.: Ueber den Gehalt des Blutes an Diphtherie Antitoxin bei gesunden Erwachsenen, Rekonvaleszenten und Bazillenträgern, . . ., Deutsch. med. Wchnschr., March 12, 1914, p. 542; abstr., The Journal A. M. A., April 18, 1914, p. 1291.

These observations are of much interest with respect to the problems of susceptibility to diphtheria. By the means of Römer's method, and also of the method described by Schick,[2] it is now possible to determine whether or not a person is susceptible to diphtheria, a question that often is of great practical importance.

LARGE CITIES AS HEALTH RESORTS

"Were I a physician, I could prescribe nothing but — 'Recipe: ccclxv drach. Londin. per annum'" (365 doses of London a year). Thus wrote a noted Londoner, Horace Walpole. "If a few days in London does your neurasthenic patient no good, his case may well be helpless and hopeless." These, the words of Dr. Clippingdale addressing the balneologic and climatologic section of the Royal Society of Medicine a few weeks ago on London as a health resort and as a sanitary city.[3] Those who are accustomed to send their patients to the mountains, the fashionable spa, the seashore or the "health resort" may ask whether this is merely subtle humor or ill-concealed sarcasm at the expense of what has been called "the healthiest, and with the exception of Madrid, the ugliest city in the world." Or are we as a profession perhaps unduly oblivious of the suitability of a large city for certain maladies, chiefly of a psychopathic or neuropathic nature? Let us follow Clippingdale's essay in this direction.

There are not a few persons who have a dread of open spaces, for example, the country. It is to such that a very large city, on account of its size and the almost infinite number of diversions it permits, appeals most remarkably. The London life is to such persons the material on which they live. There are persons who prefer looking on men and artificial things. The loneliness of the woods and green fields appals them. Many a patient sent to the monotony of the sea-shore to recuperate finds his first real joy and comfort in the return to the motley throng of some great city. In this spirit Charles Lamb once wrote: "I am naturally inclined to hypochondria; but in London it vanishes, as do other ills. The man must have a rare receipt for melancholy who can feel dull in Fleet Street."

Despite the numerous epithets of antipathy which have been recorded against the great English metropolis, despite the alleged lack of esthetic attributes, Clippingdale stoutly defends its suitability for persons suffering from certain nervous "dyscrasiae"; cases, not of true pathologic conditions, but of simple digression from the normal; cases of hypochondria, melancholia, insomnia and neuralgia of non-organic origin, the drug and alcoholic habits and morbid introspection; cases, in fact, requiring the very opposite of a "rest-cure." He insists that many means for rational psychotherapy are provided by the diversions of a great city. "Its historic, artistic and literary associations," writes Clippingdale, "its many picture-galleries and museums, its numerous places of amusement, the business activity, the Attic regions of Belgravia and the Alsatian retreats of the East End all combine to produce a state of exhilaration not met with elsewhere. In fact, it has been jocosely remarked that if Londoners themselves fell into a state of lethargy nothing would arouse them from it unless it were two Parliamentary elections in one year, together with an earthquake in the Strand." There is, of course, an underlying germ of truth in all of this. Not every man can be rescued from depression by the soothing environment of a sanatorium or the joys of the outdoor life. The heart of the city is like balm to a persistent minority who must be dealt with in the practical experience of every consultant.

As for London itself, we are reminded that the annual exodus therefrom is a "comparatively modern invention." Speaking from statistical comparison of the general mortality, it is a healthy city. Its natural advantages are enhanced by the large number of open spaces in its midst. If the climate is nothing to boast of, it must be remembered that "fog is not an atmosphere of poisonous microbes." After all, the question of liveableness in any environment is, as a rule, one of the temperament and adaptability of the individual. Americans have braved the dreaded tropics with comparative comfort and remained in perfect health. Manila and Panama have lost the terrors of climate, while the far North has become the field of pleasure-seekers. The healthfulness of an environment, urban or suburban, inland or coastwise, has become almost entirely a question of personal hygiene and mental satisfaction coupled with the indispensable accompaniments of public sanitation.

THEOBALD SMITH AT THE ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH

The recent announcement[1] of the appointment of Theobald Smith of Harvard University as the head of the projected department of animal pathology, made possible by an additional endowment to the Rockefeller Institute for Medical Research, deserves something more than passing mention. The epoch-making contributions of this distinguished American investigator are, we apprehend, not so prominently known as they deserve to be. There is a tendency in this country, in connection with all fields of scientific work, to magnify the importance of those researches which especially lend themselves to popular exposition or exhibit some scintillating feature which quickly catches the public eye. Too often as a people we forget the fundamental researches — sometimes laborious and even hazardous — on which the superstructure of some familiar practice is based. The wonders of the dynamo are allowed to overshadow the underlying experiments of Faraday; the originality of an investigator like Theobald Smith is forgotten in the contemplation of the practical results that have followed his efforts. It is a pleasure, therefore, to refer to a fine appreciation which has just appeared in *Science* from the pen of one who evidently is familiar with the history of medical microbiology.[2] We are reminded that while Dr. Smith was yet a subordinate in the Bureau of Animal Industry in Washington, he had occasion to study the Texas fever of cattle, then the cause of great economic loss to the farmers and cattlemen of that as well as other states, and of countries the world over. He found at last that the disease was caused by a protozoan parasite so small that it found a spacious abode within the purlieus of a single red cell of the blood, which it ruthlessly destroyed. Smith and Kilborne announced also that this piroplasma, as it was called, is conveyed from animal to animal through the intervention of a cattle-tick, in which the protozoan undergoes a developmental cycle on which the perpetuation of its kind depends. They further learned that cattle recovered from the fever had become immune, and though well, might indefinitely carry the piroplasma in the blood and be a perpetual source of infection for cattle fresh from another district.

The physician of to-day can well appreciate what the discovery of insects as carriers of infective microbes has meant to medicine and to mankind. This finding alone would entitle most workers to everlasting fame. Dr. Smith's epoch-making contributions did not stop with the study of the etiology of Texas fever. Smith and Salmon were the first to announce, in 1886, that animals could be immunized not only by living germs but by sterilized cultures of the dead germs. "This announcement," says the writer in *Science*, "did not seem to start even a ripple in the bacteriologic pool." The germinal idea contained in these early experiments, however, in the course of time resulted in the manufacture of antitoxin.

Probably few persons who are not experts in this field realize that the forerunner of the wonders of modern anaphylaxis is described in the *Theobald Smithsche Phänomen*, as our German colleagues early termed it. This is one of the numerous evidences of that keenness of observation which further preceded the important innovations in bacteriologic culture that are to-day indispensable. The distinctions between bovine and human tubercle bacilli emphasized by Dr. Smith are still fresh in the minds of those who have followed the long controversy on this subject.

Without recounting further details of an eminently successful career we may congratulate the Rockefeller Institute, already so fortunate in having made itself an unsurpassed center for medical research, on the discriminating selection of another distinguished and productive member.

THE AQUEOUS HUMOR

Various structures of the eye, such as the lens, suspensory ligament and vitreous humor, receive no direct vascular supply, but depend on the intra-ocular fluid for their nutrition. This aqueous humor is continually renewed by the transudation of fluid from the blood-vessels of the ciliary processes into the anterior part of the vitreous cavity, the amount increasing with a rise of blood-pressure in the capillaries, or a fall in intra-ocular pressure. The latter in turn is affected by the blood-pressure and by variations in the escape of the fluid through the filtration angle. If the anterior angle becomes blocked as the result of inflammatory or other changes, the intra-ocular pressure rises gradually far above normal. This may seriously affect the circulation of blood through the retinal vessels, so that atrophy of the retina is produced as well as disturbances of the nutrition of the eye.

The increased intra-ocular tension in glaucoma is well known. The changes in the chemical composition of the aqueous humor not only in local eye disturbances, but also because of alterations in the quality of the blood, are less evident. The involvement of the eye in systemic or constitutional diseases is not unfamiliar. In diabetes the sight is often defective, and not infrequently the detection by an oculist of a commencing or well-developed cataract or a retinitis first arouses suspicion of a possible underlying disease. To speculate extensively on the immediate effects which the aqueous humor can have on the eye structures which it bathes and nourishes is of little avail until the factors which determine the chemical composition of the intra-ocular fluid are somewhat better understood. Like the cerebrospinal fluid, with which it has frequently been compared, the aqueous humor has generally been classed as a slightly modified lymph. This simple point of view does not take into account the possibility that the intra-ocular fluid is not a mere transudate, but is dependent for certain details of its composition on the selective function of the cells through which it originates. In contrast with true lymph, the aqueous humor normally contains no leukocytes, and its content of protein is extremely low (0.025 to 0.02 per cent.). The characteristics of such a fluid resemble those of some glandular secretions rather than those of tissue lymph, and for this reason one cannot prophesy precisely what changes it may undergo in connection with alterations in the nutrition of the body as a whole.

---

[2] T. M. P.: Professor Theobald Smith and a New Outlook in Animal Pathology, Science, 1914, xxxix, 751.

Most of the known facts concerning the aqueous humor have been learned from analyses made on fluid obtained post mortem. Under such conditions chemical changes almost invariably have intervened. Dr. Ask[1] of the institute for medical chemistry at Lund in Sweden has lately investigated the sugar content of the aqueous humor in both man and animals, obtaining the fluid by drainage from the anterior chamber. His analyses show a close relationship between the concentration of sugar in the fluid and that in the circulating blood. Under ordinary normal conditions with a blood-sugar content of from 0.1 to 0.13 per cent., that of the aqueous humor will be from 0.12 to 0.15 per cent.; the primary fluid and that formed later show the same sugar concentration. When by experiment the content of sugar in the blood is caused to vary, the resulting hyperglycemia is accompanied by a parallel rise in the sugar content of the intra-ocular fluid. In pronounced pathologic conditions, however, when the excursions of the blood-sugar from the normal are very extensive, the content in the aqueous humor may fail to reach the blood maximum. This may be due to the slowness of the exchange between the blood and the eye-fluid, and perhaps also in part to some regulating secretory mechanism in the interior of the eye. In a case of human diabetic cataract, the sugar content and aqueous humor alike were found above normal (0.24 per cent.). Although in such conditions the intra-ocular fluid and the blood agree in composition, in other conditions, such as glaucoma or seclusio pupillae, in which enforced stagnation of the fluid in the anterior chamber exists, a diminution of its sugar content is by no means excluded. The interrelations between the composition of the blood and the fluid in the interior of the eye point to the desirability in ophthalmologic practice of recognizing the existence of hyperglycemia, especially since in diagnosis the estimation of sugar in the blood is being used in connection with the older routine examination of the urine for evidence of glycosuria.[2]

HEREDITY VERSUS FOOD IN DEVELOPMENT

It has become a dictum among those most concerned with the physiologic function of the mammary gland that "breed rather than feed" determines the quality and output of milk. The food of an animal may be varied within very wide limits without altering the composition of its milk, provided that the ration is sufficient in amount. The only constituent which is known to be altered in milk by changes in the food-supply of the mother is the fat. The composition of butter may be affected somewhat by the food supplied to the cow; but normally little if any influence on the chemical make-up of the milk can be produced by wide variations in the mineral content of the food.

The question as to what extent, if any, the structure and development of the fetus can be affected by the character of the maternal diet is somewhat analogous to that which concerns the possible alterations in the milk produced by the mother. In a sense both the milk and the fetus may be regarded as produced by a specific organ; the one by the mammary gland and the other by the placenta. An idea current among cattle-raisers is that a high mineral content in the ration will cause excessive skeletal formation in the fetus and consequent difficulties at its birth. Similar views are sometimes expressed relative to the development of the human fetus. In view of the general specificity and uniformity of composition and structure exhibited by the normal products of cellular or glandular activity in the animal organism — a feature which is expressed by the fixity of species and the constancy of the products thereof — and, further, that many ingested substances fail to traverse the placenta directly, it might be expected that diet, so long as it is abundant enough, would exercise slight modifying influence on the structure of the fetus. That is, selective action on the part of the placenta with a definite control of the mineral content of the fetus might be expected, the size of the skeleton being fixed by the germ-plasm and controlled by heredity, rather than subject to the quantity of inorganic matter consumed by the mother.

---

[2] The Variations in the Content of Sugar in the Blood, editorial, The Journal A. M. A., Jan. 10, 1914, p. 131. McLean, F. C.: The Sugar Content of the Blood and Its Clinical Significance, The Journal A. M. A., March 21, 1914, p. 917.

It has been remarked that "assumptions in nutrition are dangerous." The questions raised in the foregoing discussion cannot well be tested by experiment on human beings; but the effect which a high lime-intake by the mother may have on the skeletal development of the fetus has been subjected to experiment in the domestic animals.[1] Since grains are deficient in calcium, farm rations made up wholly of them will not supply to growing animals a sufficient amount of this element. For this reason growing or breeding swine, fed entirely on grain, should receive an additional supply of calcium, as calcium carbonate or calcium phosphate or in leguminous hay. Any drain on the organism with consequent loss of calcium is thus averted. The new Wisconsin experiments, however, have shown that though the nutrition of the mother has a great influence on the offspring, the size is not modified by the liberal supply of any one element. Although a high calcium ration, containing over five times as much lime as the standard ration, was added to the feed of the mother during the entire period of gestation, no evidence was gained that the skeleton of the fetus was increased in any dimension or in calcium content thereby. As Hart and his co-workers remark, if size can be influenced at all by the quantitative relation of the nutrients supplied, it is clear that many factors are involved and not a single mineral element. Size is in a very large measure fixed by heredity.

Current Comment

CREATININ IN THE BLOOD

With the advent of the newer accurate and rapid methods for the clinical examination of the blood, chemical statistics on this fluid are accumulating to a surprising degree. Elaborate series of data are already available concerning the sugar-content and the concentration of various types of metabolic waste-products or catabolites, such as urea, uric acid and ammonia, in both health and disease. The mention of hyperglycemia or of an increase in the percentage of nonprotein nitrogen in the blood begins to sound almost as familiar as the every-day reports of the clinical laboratory with respect to urinary findings. Somehow the problems of the composition of the blood appeal to those interested in the phenomena of abnormality as something preeminently significant. The unique rôle of the blood in the distribution of both food and waste gives an exceptional interest to the ascertained facts about it. Until very recently, owing to the lack of suitable analytic procedures, the number of creatin literature has been exceedingly small. With their usual mastery of technic, Drs. Folin and Denis[1] of the Harvard Medical School have undertaken an elaborate series of such determinations in order to learn whether in pathologic conditions there is any specific retention of creatinin similar to the specific retention of uric acid in the blood in gout.[2] No such condition could be brought to light in the examination of the blood of two hundred patients at the Massachusetts General Hospital. Ordinarily, the content of creatinin ranges from 1 to 1.5 mg. per hundred grams of blood. Except in extreme conditions of retention approaching anuria the creatinin in the blood remains at the normal level. The completeness of the creatinin excretion in man is exceeded only by the still more complete removal of ammonium salts. It is interesting to note that the figures obtained from the common domestic animals do not differ materially from those derived from analysis of human blood, except in the case of birds. The absence of creatinin from the blood of these species confirms Paton's discovery that creatinin is not a normal waste-product of birds.

MORE MEDICAL JOURNALS?

The newest venture in the domain of medical journalism, represented by the publication of the *Hamburgische medicinische Ueberseehefte*,[3] raises the old question as to the desirability of the ever-increasing numbers of such enterprises. We have long believed that specialization in this field should be encouraged only so far as existing mediums fail to provide for the suitable expression of current medical experience and discovery. Far more can be accomplished in many directions by the unifying of forces and the better utilization of existing opportunities than by the dissipation—we cannot always call it expansion—of effort. The improvement and advancement of scientific medical journalism, and thereby of the sciences and arts that it serves, is not necessarily secured by more pages in a larger number of publications, but frequently far better by a critical editorial policy which, acting for the good of a profession rather than the promotion of individuals, rejects the commonplace and untenable, and expects even the best of its contributions to conform to the highest standards of expression. Gallons of ink have been spilled in useless writing, and reams on reams of paper filled with reiterated histories, useless protocols, unprofitable controversy and preposterous trivialities—all to make so-called literature. The demands for novelties are frequently only the expression of personal ambitions rather than the crying needs of science or practice. With this preface we may proceed to the examination of the new journal emanating from the Eppendorfer Krankenhaus in Hamburg under the editorial supervision of Dr. Brauer, the director of the hospital, and Dr. Hegler of its staff. It is issued, we are told in the introductory notice, to meet the special needs of German or German-speaking physicians who are engaged in practice in foreign lands. We are further told that the numerous existing medical periodicals, despite their admitted excellence, offer, aside from results of purely scientific value, too many contributions which have only a transitory interest or concern only the specialist and theorist. It is the same set of statements that has appeared in correspondence of The Journal from time to time in the column on Knocks and Boosts, so that this point of view will not be unfamiliar to our readers. The *Uebersechefte* are designed to act as a medium of scientific communication with those physicians who are settled on distant shores; to furnish to these colleagues authoritative accounts of the permanent acquisitions of medical science and the newest devices in practice. They are to be devoted to German progress and supported by German societies that have foreign interests. All national propagandas have a certain honorable justification. We have frequently spoken with pride of the publications of our own Bureau of Science in the Philippines. The real test of their justification for existence lies in the good accomplished; and this, in turn, depends on the intellectual pabulum supplied. The collaborators of the new enterprise are scattered from Buenos Aires to Shanghai, from Constantinople to New York, Dr. Flexner being the representative from the United States. The first number (53 pages) of the *Uebersee-hefte* opens with a theoretical discussion and classification of "diatheses" by von Behring; papers on cardiac therapy, by Brauer; emetin treatment of amebic dysentery, by Ruge; the etiology of leprosy, by Unna, etc.; the usual book reviews and a few unimportant news items. Wherein the publication is expected to meet the needs of its subscribers better than do the excellent well-known medical weeklies of Germany, remains to be demonstrated; it is not shown in the initial number.

McCLURE'S MISTAKE

On another page,[1] in reply to numerous inquiries, we have stated once more the truth regarding the scopolamin-morphin method of producing analgesia in labor and its unreliability and danger. The present effervescence of medical interest in this subject is excited by an outburst of enthusiasm concerning the treatment as applied at Freiburg, by Krönig and Gauss, published in the June issue of *McClure's*. The article appears under the signature of two women, evidently not medical authorities, and contains frequent quotations of statements credited to Krönig and Gauss. In an address delivered by Krönig before various societies when here last November, published in the May issue of *Surgery, Gynecology and Obstetrics*, statements are made almost identical with some of those in the *McClure's* article. We hesitate to believe that either Krönig or Gauss would instigate or endorse such a sensational puff for themselves, but so clear does the evidence appear that this impression is almost forced on us. If the publication was sanctioned by either or both of them it indicates an advertising initiative which bids fair to rival Friedmann. It is needless to explain to physicians that many of the statements contained in the *McClure's* article are ridiculous. As usual, not the physician, but the credulous and innocent public will be harmed by this unfortunate exploitation.

GET OUT OF THE HABIT

Recently we received a manuscript from a man standing high in the profession, in which, among other things, a certain much-advertised proprietary medicine was recommended. The author was asked whether he was sure that he was getting good results from the preparation. His reply was instructive. To quote:

> While I have used this preparation for years, I must say that I have not seen results that I could attribute to it directly, and its use has become merely a habit. As it has not been accepted by the Council, I shall drop the use of it, as I am not at all convinced that it is of any value.

Unquestionably, there are thousands of physicians who, if they would, might make as honest a statement as the one quoted.

ANATOMIC MODELS

The wide-spread use of the Born method of wax-plate reconstruction in the preparation of models illustrating the form and relations of minute anatomic structures has led to the preparation of a large number, representing the most diverse types of morphologic tissue components. Heretofore it has been necessary to send these valuable original models abroad in order to secure replicas. The trouble, expense and risk of accident incurred in transporting such fragile articles as, for example, a reconstruction of the glomerulus of the kidney, in connection with conditions difficult to meet have discouraged those desirous of securing such models. The Wistar Institute of Anatomy in Philadelphia, an institution which is not only serving to promote research along broad lines of biology, but also functioning as a clearing-house in matters of scientific publication, etc., has added another to its useful activities by establishing a department for what might be called the publication of original models. The institute will receive original anatomic models, produce as many replicas as may be subscribed for and distribute them for the actual cost of production. By this means teachers and students of anatomy will be enabled to examine more of the original models resulting from research in our best laboratories. According to the *Anatomical Record*,[1] the work will be done under the personal supervision of Dr. B. Eric Dahlgren, a well-known expert of wide experience in the production of biologic models. The first replica will be made under the supervision of the author of the model. The model will be retained at the Wistar Institute as a guide in the production of others.

Medical News

CALIFORNIA

New Officers.—Los Angeles County Medical Association, Santa Monica Bay branch, April 6: chairman, Dr. C. P. Thomas; secretary, Dr. Byron Palmer.

Immunization of National Guard.—To perfect plans quickly to render the national guard of the state immune against small-pox and typhoid fever, a conference of medical officers was called, May 11, by Maj. Charles W. Decker, commanding field hospital No. 1, at the Armory Exposition Park, Los Angeles.

Sanitation of Camp of "Army of the Unemployed."—Dr. Hugh Beattie, health officer of Sacramento County on an inspection of the camp of the "Army of the Unmeployed," north of Sacramento, reported the conditions to be very bad and recommended the dispersal of the "army." In this he was not sustained by the state board. Sanitary Inspector Ross employed by the State Board of Health, after an investigation of the conditions, made such recommendations to the board that instructions were given to the local health officer to have the nuisance abated.

Rabies.—In March the supervisors of Sonoma County repealed the dog-muzzling ordinance which had been in force in that county since Dec. 4, 1913. The secretary of the State Board of Health immediately ordered the county quarantined under existing state laws. The order was subsequently modified to require the muzzling of dogs within those townships of the county most heavily infected with rabies. Los Gatos Canyon District of Fresno County was quarantined for rabies under Chapter 369 of the Statutes of 1913 on account of the presence of rabies in dogs, cattle and horses.

Fly-Traps Required by Ordinance.—Richmond has an anti-fly ordinance requiring that every person in charge or control of any store, market, restaurant or other place where food or foodstuffs are sold, served or dispensed, and every owner or person in charge of a public stable, shall maintain in his place of business one or more fly-traps properly baited. The size of these traps is fixed at a minimum of 500 cubic inches, and it is made the duty of the Health Department to inspect the traps from time to time to see that they are efficiently maintained. Under this ordinance the time of one man is given to baiting and attending to the traps.

Mosquitoes in California.—The secretary of the State Board of Health has requested the surgeon-general of the United States Public Health Service to take such action as might be necessary to prevent the introduction of *Stegomyia calopus* into the state. It is believed that the chief source of danger of entry of the yellow-fever mosquito is from Texas and Mexico by way of the railroad trains coming from those sections. The surgeon-general replied that the matter had been referred to Dr. Thos. R. Crowder, superintendent of sanitation of the Pullman Company, for an opinion as to the best method of handling the problem.

Personal.—Dr. and Mrs. John C. Taylor, Los Angeles, have been appointed medical missionaries to India by the synod of the reformed Presbyterian Church, and will be stationed at Patiala. They will leave for their post of duty early in September.——Mr. H. C. Moore, United States food and drug inspector, has been appointed food and drug inspector of the State Health Board without salary.——Mr. J. J. Rosenthal, Mr. Geo. L. Bell and Mr. Carlton H. Parker have been appointed inspectors for the State Health Board, and the commission of immigration and housing of California has been notified of the appointments.——Miss Violet M. Bathgate has been appointed assistant bacteriologist at the State Hygienic Laboratory, vice Miss Ethel Skolfield who has resigned.

CONNECTICUT

New Officers.—Norwich Medical Society, May 18: president, Dr. James J. Donohue; secretary-treasurer, Dr. Lester E. Walker.

Gift to Yale Medical School.—At its spring meeting, May 29, the General Education Board (Rockefeller Foundation) gave $500,000 to the Yale Medical School on condition that the school procure complete teaching and medical control of the New Haven Hospital and that the teachers in the main clinical branches be placed on the full-time or university basis.

State Society Elects.—The Connecticut State Medical Society held its one hundred and twenty-second annual meeting at New Haven, May 20-21, under the presidency of Dr. D. Chester Brown, Danbury. The following officers were elected: president, Dr. Oliver C. Smith, Hartford; vice-presidents, Dr. Stephen J. Maher, New Haven, and John B. Kent, Putnam; secretary, Dr. Marvin McR. Scarbrough, New Haven (reelected); treasurer, Dr. Joseph H. Townsend, New Haven, and delegate to the American Medical Association, Dr. D. Chester Brown, Danbury. Hartford was selected as the next place of meeting. The society endorsed the work of the State Tuberculosis Commission and of the state sanatorium for tuberculosis.

GEORGIA

Personal.—Dr. John F. Lancaster, Forsythe, has been appointed quarantine and health officer of the port of Mobile, Ala.——Dr. Benjamin S. Purse, Savannah, has been elected chief surgeon of the Army of the Tennessee.

Hospital for Tuberculosis and Pellagra.—The commissioners of Bibb County, the Bibb County Medical Society, the City Council of Macon, and the Macon Board of Health are uniting their efforts for the establishment of a special hospital for the treatment of patients suffering from tuberculosis and pellagra.

IDAHO

Personal.—Dr. Franz H. Brandt and family, Boise; Dr. Clifford M. Cline, Idaho Falls, and Dr. William F. Howard, Pocatello, sail for Europe this month.

New Officers.—Southern Idaho District Medical Society at Caldwell, April 28: president, Dr. Samuel J. Miller, Caldwell; secretary-treasurer, Dr. Robert L. Glase, Boise. The next meeting will be held at Boise in July.

ILLINOIS

Personal.—Dr. and Mrs. Harry B. Bailey, Rockford, sailed for Europe, June 3.——Dr. Effie L. Abbott, a member of the Anna State Hospital, has been transferred to a similar position at the Elgin State Hospital.

Health Talks.—The laboratory of bacteriology of the University of Illinois, Champaign-Urbana, under the direction of Assistant Professor Otto Rahn, has arranged a series of lectures on public health to be given weekly during the first semester of 1914-15.

News about Sanatoriums.—During the last year, 166 patients were treated at the Chicago-Winfield Tuberculosis Sanatorium at Winfield, at a cost of about $1.17 per day. Dr. James L. Anderson, Pittsburgh, Pa., has been elected medical director of the institution, to take office June 1.——The supervisors of La Salle County have awarded the contract for the construction of the new tuberculosis sanatorium at the county farm for $7,643.——At a meeting of the Kane County Medical Society, at Geneva, May 6, the association heartily endorsed the proposition for a Kane County Anti-Tuberculosis Sanatorium, and pledged their support. The supervisors of Kane County have already appropriated $5,000 toward the purchase price of a site for the sanatorium.

Chicago

Bust Unveiled.—A convocation of the College of Medicine of the University of Illinois will be held June 10, in honor of the unveiling of a bust of Dr. Daniel A. K. Steele.

Personal.—Dr. Frances Dickinson has been reelected president of the Artcraft Institute Guild.——Dr. Robert C. Reimche has assumed charge of the Chamberlain, S. Dak., Sanitarium.

Rush Medical Alumni to Meet.—The week of June 8-13 will be observed as "Homecoming Week" by Rush alumni. Special clinics will be held at the college and by alumni practicing in the city. The faculty will entertain the alumni with a banquet to be given June 10, at which Dr. Frank Billings will preside.

Free Ice to be Distributed to Poor.—The Consumers' Company announce that free ice certificates would be available for needy and destitute families. The offer made first for all the ice needed for the Visiting Nurse Association has been expanded to include the Infant Welfare Society, the United Charities and every other recognized charitable organization of the city, including the Volunteers of America, Salvation Army and all deserving cases reported by clergymen and physicians.

INDIANA

Personal.—Dr. and Mrs. Charles A. Pfafflin, Indianapolis, sailed for Europe, May 30.——Dr. Thomas B. Eastman has been appointed a member of the Indianapolis Board of Health, vice Dr. Moses Thorner, resigned.

Marked Increase in Measles.—Reports of 2,628 cases of measles in Indiana were made to the State Board of Health for the month of April. Twenty-eight deaths from the disease were reported, and sixty-three counties recorded the disease as prevalent within their borders. The increase over the preceding month was alarming.

Sanatoriums Quit.—The Rockwood Sanatorium Company, which closed its tuberculosis sanatorium at Danville in June last, gave notice to the secretary of state, May 14, of its dissolution as an incorporated body.——The Plymouth Sanatorium and Hospital has been closed by order of the Board of Directors, and will be offered for sale. The building was erected in 1910 at a cost of more than $50,000. Dr. Novitas B. Aspinwall, who has been in charge of the sanatorium, will conduct a similar institution in Plymouth in connection with Miss Aura Southwick.

IOWA

Personal.—Dr. and Mrs. Bert A. Bowers and family, Granville, left for Europe, May 14.——Dr. Millard F. Pritchard announces his retirement after forty years of continuous practice in Cherokee.

Iowa Medical Women Elect.—At the annual meeting of the Iowa State Medical Women, held in Sioux City, May 14, the following officers were elected: president, Dr. Kate S. Harpel, Boone; vice-presidents, Drs. Jeanette F. Throckmorton, Chariton, and Mary K. Heard, Iowa City; secretary, Dr. Margaret Armstrong, Des Moines, and treasurer, Dr. Grace F. H. Jerger, Waterloo.

KANSAS

Personal.—Dr. John B. Dykes, Lebanon, is a candidate for Congress from the sixth district of Kansas, on the Republican ticket, and has no opponent of his party, and as the district is normally Republican, it seems probable that he will be elected.

Physicians Exonerated.—In the case of Drs. Charles E. Bowers and Thor J. Jäger, Wichita, charged with negligence in treating and operating on Mrs. Nellie Stout, Hazleton, the court held that both doctors had used their best judgment, and the jury, without leaving the jury-box, rendered a verdict for the defendants.

KENTUCKY

Personal.—Dr. W. Ed Grant has been reappointed health officer of Louisville.——Dr. Borowski has been appointed medical inspector of the Department of Health of Louisville.

University News.—Dr. Henry Enos Tuley has succeeded Dr. W. Ed Grant as dean of the medical department of the University of Louisville.——Hon. D. W. Fairleigh, president of the board of trustees of the university, has resigned and been succeeded by Hon. Arthur Y. Ford.——Dr, Virgil E. Simpson has been elected president of the alumni of the university.

Hospital Notes.—The State Board of Control has decided that a hospital for the tuberculosis patients of the Eastern Kentucky Hospital for the Insane be erected at Lexington at once. The structure will cost $300,000.——Dr. Joseph A. Stucky, Lexington, and representatives of the State Board of Health, State Anti-Tuberculosis Association, and American Red Cross, have established a clinic at Oneida for the treatment of trachoma, tuberculosis and hookworm.

State Hospital Changes.—Dr. Frank L. Peddicord, Burlington, has succeeded Dr. William E. Gardner as superintendent of the Kentucky Hospital for the Insane, Lakeland. Dr. Gardner has returned to his former home in Hardin county.——Dr. William E. Render, Brownsville, assistant physician to the Eastern Kentucky Hospital for the Insane, Lexington, has been appointed first assistant physician to the Central Kentucky Hospital for the Insane, Lakeland.——Dr. W. E. Campbell, Bowling Green, first assistant surgeon at the Hopkinsville State Hospital, has been appointed second assistant physician at the Eastern Kentucky Hospital.——Dr. H. G. Sanders, Campbellsville, has been appointed first assistant physician at the Hopkinsville State Hospital.

MARYLAND

Medical Board Reappointed.—The Police Board of Baltimore has reappointed the Board of Medical Examiners which consists of Dr. James M. Craighill, chief police physician, and Drs. Hubert C. Knapp, Thomas P. McCormick, Walter F. Sowers and Elliott H. Hutchins.

New Officers.—Montgomery County Medical Society, April 25: president, Dr. John L. Lewis, Bethesda; secretary, Dr. Claiborne H. Mannar, Rockville.——Cecil County Medical Society: president, Dr. Harry A. Cantwell, North East; secretary-treasurer, Dr. Howard Bratton, Elkton.

Personal.—Dr. Tedrow S. Keyser of the staff of the Pitts Clinic, Baltimore, has resigned to accept a position with the Neurological Institute, New York City.——Dr. Wilbur P. Stubbs has been appointed medical examiner of the schools of Baltimore, vice Dr. Richard A. Urquhart, deceased.——Dr. Arthur H. Hawkins has been appointed representative of the Cumberland Academy of Medicine on the State Board of Health.——As a result of friction which is said to have existed several months between the mayor and Health Commissioner Nathan R. Gorter, a request was made, May 18, for the resignation of Dr. Gorter, to take effect immediately. Dr. Gorter has not resigned.——Dr. Jacob Thorkelson, Baltimore, has moved to Dickenson, N. Dak., where he will be associated with Drs. Homer A. Davis, Jesse W. Bowen, and Justus Ohage, Jr.

MASSACHUSETTS

Governor Selects Heiser.—Governor Walsh has confirmed the story that he has selected Surg. Victor P. Heiser, U.S. Public Health Service for health commissioner, of Massachusetts, in the event of the passage of the bill reorganizing the State Board of Health.

Typhus Fever at Granite and Quincy.—May 20, 1914, a case of typhus fever was notified at Graniteville in an immigrant arriving at Boston April 23 on the steamship *Rhaetia* from Hamburg. He was taken ill May 8. Another case from the same vessel was found at Quincy. The patient was taken ill May 3.

New Officers.—Hampshire District Medical Association at Northampton, May 15: president, Dr. Edward W. Brown; secretary, Dr. Joseph B. Collins, both of Northampton.——Franklin District Medical Society, at Greenfield, May 12: president, Dr. John E. Urquhart, Ashfield; secretary,treasurer, Dr. Halbert G. Stetson, Greenfield.

New Secretary of Faculty.—The executive committee of the trustees of Tufts College, Boston, approved the appointment of Dr. Frank E. Haskins as secretary of the medical and dental faculties in place of Dr. Frederick M. Briggs, who will retire from active service September 1, to become professor of surgery and secretary of the medical and dental faculties, emeritus.

MINNESOTA

New Officers.—Rice County Medical Association at Northfield, May 14: president, Dr. Arthur C. Rogers; secretary-treasurer, Dr. Frederick U. Davis, both of Faribault.

Personal.—Dr. Peter C. Davison, Clara City, has sailed for Europe.——Dr. H. W. Hill will assume his duties as executive secretary of the Minnesota Public Health Association, July 1.

Sanatorium Notes.—Lincoln, Lyon, Redwood, Pipestone, Murray and Cottonwood counties have agreed jointly to construct a sanatorium for patients of those counties, and they have invited Rock, Noble and Jackson counties to unite with them. The counties have already levied a tax of 0.6 of a mill, and if the other counties take similar action, the amount will be raised to $50,000. This, with the amount agreed to be paid by the state, will make the total amount available for his institution $100,000.——Union, Chippewa, Renville and Yellow Medicine counties have considered and rejected the project of a tuberculosis sanatorium at Granite Falls. The chief argument appears to be that Lac Qui Parle County should have a sanatorium of its own.——St. Lewis County is to have a tuberculosis sanatorium to cost $50,000. One half of this expense is to be met by the state.——Work on the construction of the new Goodhue County Sanatorium, near Cannon Falls, will be commenced this month. The building is to cost $20,000.

NEW YORK

New Officers.—Mount Vernon Medical Society, May 15: president, Dr. Charles Krumwiede; secretary, Dr. Frank A. M. Bryant.

Personal.—Dr. John W. Conks, Syracuse, has been appointed professor of pathology in the North Dakota State University.

Sanatorium to Open.—The Metropolitan Life Insurance Company announces the dedication of its tuberculosis sanatorium for employees at Mt. McGregor, Saratoga County, June 20, at noon.

Antitoxin Farm.—The Hungerford Farm, Guilderland, has been sold to the state for $9,500, and the state will establish a farm for antitoxin and hygienic laboratories, which have been maintained in Albany for several years.

New Clinic Established.—Physicians of Southold and Shelter Island have organized a clinic which is to meet regularly at the Eastern Long Island Hospital, Greenport. ——The physicians of Patchogue are about to open a free dispensary.

Communicable Diseases.—The number of cases of scarlet fever in the Auburn prisons has reached nearly 80, most of the sufferers being in the women's prison. The prison staff of four physicians has received additional help from the State Health Department. It is said that the cases are all mild.——There is an epidemic of measles at Princes Bay, Borough of Richmond. In the neighborhood of 100 cases have been reported.

Child Welfare Campaign Exhibit.—An extensive campaign for the reduction of infant mortality in the state by means of lectures, literature and other forms of education and publicity has been inaugurated by the State Department of Health and itineraries for three exhibits are being prepared. They are planned not only to be instructive to mothers but to demonstrate the necessity and value of the visiting nurse, infant welfare stations, and other welfare work. A series of public meetings will be arranged for each city visited, and it is hoped that permanent welfare work will be organized in every city visited by the exhibits. In connection with this campaign a copy of the department's booklet on "How to Save the Babies" is being mailed to every mother in the rural districts of the state on the receipt of the birth certificate of her child.

Report of Vital Statistics.—A warning has been issued to physicians and registrars throughout the State in regard to reporting vital statistics. It is the purpose of the department to use to its full extent the authority with which it is vested to secure obedience to the provisions of the law in relation to vital statistics. The following is the notice:

> To Physicians: The attention of all physicians is called to the provisions of the said law.
>
> Every physician in attendance upon a birth must, within five days after such birth, file with the local registrar a certificate thereof on the prescribed form. Every medical certificate of death must be made out by the physician, last in attendance, in the form and manner prescribed. Every physician, who has not already done so, must register immediately with the local registrar.
>
> All births which have not been reported within the period prescribed by law may be registered with the State Department of Health up to May 30 without penalty. After that date, it is the purpose of the Department of Health to take such legal action as seems necessary to secure full registration of all births occurring in this State, and to enforce the penalties prescribed by law.

Health News.—This is the title under which the State Department of Health has issued its last *Bulletin* and the first one for which Dr. Hermann M. Biggs, state commissioner of health, is entirely responsible. It is called the "Principal's Number" and is devoted to health work as it applies to the school, and to pointing out the function of the school in public health education. In his letter to the principals of the state Dr. Biggs states that it will be the purpose of the department so to prepare the *Monthly Bulletin* that it will be of special service to the school principals throughout the state as well as to the local health officers and other health workers for whom it is particularly designed. It will be the aim of the editor to include in each number material which is timely and important for children to know. This will be summarized under the heading "School Health Lessons." Dr. Biggs asks the principals to see that the gist of this monthly lesson shall be read and explained to the children either by the principal or by some teacher appointed by the principal at a designated assembly when both teachers and pupils are present.

New York City

Illegal Sale of Hypodermic Needles.—During the past week four druggists have been arrested and held on the charge of having sold hypodermic needles to persons other than physicians and without the prescription of a physician.

New Officers.—Flatbush Medical Society at Brighton Beach Casino, May 8: president, Dr. Walter D. Ludlum; secretary, Dr. Stanley B. Thomas, both of Brooklyn.——Valentine Mott Society, New York City: president, Dr. Emil Heuel; secretary-treasurer, Dr. Joseph E. Lumbard.

Movies Teach Health Work.—The Motion Picture Exhibitor's Association of Greater New York has offered the Health Department the services of more than 800 moving picture theaters for the educational work of the Department. The start was made on May 16 when hundreds of theaters displayed slides calling attention to the "Clean-up" campaign inaugurated by Commissioner Goldwater. This will be followed by announcements concerning flies, typhoid fever, care of babies, etc.

Death Certificates in New York City.—During 1913 almost 65,000 certified copies of death certificates were issued by the Department of Health, as set forth in the *Weekly Bulletin* May 23. It is said that fully 80 per cent. of these were used in obtaining funds to bury the deceased person. The savings banks require them before money for burial purposes will be paid from the accounts of deceased depositors, many transcripts are required on account of the collection of insurance policies, the probate of wills in this and foreign countries, etc. Certificates sent abroad must be vised by the consul representing that country.

Hospitals and Isolation Wards.—In view of the fact that the Sanitary Code requires every public hospital and dispensary in the city of New York to provide and maintain a suitable room or rooms for the temporary isolation of persons suffering from infectious diseases, a survey of the hospitals and dispensaries of the city has revealed the fact that a considerable number of institutions have failed to comply with this requisition. It was discovered that 11 small hospitals and 39 dispensaries make no provisions for isolation. The department has appealed to the managers and the medical staffs of these institutions urging that they make an earnest effort promptly to meet the requirements.

Insurance Companies Cooperate with Health Department in Public Health Education.—In carrying on an extensive health campaign, the Department of Health has frequently found it difficult to reach large numbers of people quickly. After a conference with the representatives of the Metropolitan and Prudential Life Insurance companies, these companies have placed the services of their agents at the disposal of the Department of Health for the distribution of public-health literature. This means approximately 3,000 agents visiting the homes of 750,000 families weekly. The department seeks further cooperation along these lines and will be pleased to hear from organizations which are prepared to contribute assistance.

Personal.—Dr. Mark J. Schoenberg has been awarded, by the New York State Medical Society the Lucien Howe prize for his research work on ocular anaphylaxis.——Dr. Jacques Loeb of the Rockefeller Institute for Medical Research, has been elected correspondent of the French Academy of Science, in the section of anatomy and zoology, to succeed the late Lord Avebury.——Dr. Smith Ely Jeliffe has been elected a corresponding member of the Paris Neurologic Society.——Dr. Charles Bolduan has been appointed head of the new Bureau of Public Health Education of the Department of Health.——Dr. S. Adolphus Knopf gave the opening clinic, on June 2, for a postgraduate course to be inaugurated by the Bruchesi Tuberculosis Institute, Montreal.

Cancer as a Public Health Problem.—The *Monthly Bulletin* of the Department of Health of the city of New York is devoted to information concerning cancer. Curtis E. Lakeman, executive secretary of the American Society for the Control of Cancer, gives a statement of the cancer problem as it is at present understood, together with information and warnings to the public for the control of this increasing, fatal disease. Some statistics are given which show that the mortality from cancer in the registration area of the United States per 100,000 population increased from sixty-three in 1900 to seventy-seven in 1912. In New York State the rate has increased from forty-three for the three-year period 1887-1889 to eighty-six for the period 1911-1913. Warning is given against radium fakes and other fake cancer cures.

Administrative Control of Whooping-Cough.—A plan for the supervision and treatment of whooping-cough has been developed by the Department of Health. A survey has recently been completed of the institutions, hospitals and dispensaries of the city, with a view to determining what institutions treat whooping-cough at the present time, what institutions desire to maintain whooping-cough clinics, and what facilities they possess for dealing with this disease. All together 116 institutions were visited; of these 78 reported that they had no patients with whooping-cough applying for treatment; only five have a district physician caring for whooping-cough cases in their homes; 67 institutions admitted that their physicians did not report all cases of whooping-cough to the Department of Health, and only four institutions maintained and supported classes for treating cases of whooping-cough on the premises. Three of these were hospitals and one a dispensary. The investigation shows why whooping-cough is so prevalent in this city and why it has failed of administrative control. The department will take up the question with the Associated Out-Patient Clinics and the hospitals, and it is hoped that before long adequate facilities for the care of patients suffering from whooping-cough will be provided.

OHIO

New Officers.—Perry County Medical Society reorganized at Lexington, April 29: president, Dr. Calvin B. Holcomb, Corning; secretary-treasurer, Dr. Robert W. Miller, Hemlock.

Personal.—Dr. Walter E. Obetz, Columbus, has been appointed assistant epidemiologist of the staff of the Ohio State Board of Health.——Dr. George Goodhue, Dayton, who was operated on, May 12, at Rochester, Minn., for intestinal ulcer, is reported to be doing well.——Dr. William H. Buechner, Youngstown, was given a dinner in honor of his fiftieth birthday anniversary by members of the medical profession and others, May 23.——Dr. and Mrs. Charles U. Hanna, Zanesville, sailed for Europe June 4.——Dr. and Mrs. Charles M. Neldon, Coshocton, will sail for Europe June 12.

To Promote Medical and Dental Supervision of School-children.—Dr. Porter B. Brockway, Toledo, recently elected president of an organization for the promotion of medical and dental supervision of children in rural as well as in city schools, announces the following committee for cooperation with the superintendent of the public schools: Dr. William H. Peters, health officer of Cincinnati; Dr. Erwin A. Peterson, chief medical inspector, Cleveland; Dr. Herbert M. Platter, Columbus; Dr. Eugene F. McCampbell, Columbus, secretary, State Board of Health, and Dr. F. R. Chapman, Columbus, secretary of the Ohio State Dental Society.

Cincinnati

Hospital Staff Election.—At the annual meeting of the staff of the Cincinnati Hospital, May 28, the following officers were elected: president, Dr. Benjamin K. Rachford; vice-president, Dr. Robert Carothers; secretary, Dr. Meyer L. Heidingsfeld; and treasurer, Dr. Edwin W. Mitchell.

Alumni Meeting.—The Alumni Association of the Ohio-Miami Medical College has arranged an elaborate clinical program, beginning June 10. On this day, Dr. William E. Haggard, Nashville, Tenn., will hold a clinic on surgery, and Dr. Christian R. Holmes, Cincinnati, one on otology. On June 11, Dr. Wendell C. Phillips, New York City, will lecture on the "Conservation of the Hearing Function," with illustrative cases, and Dr. George A. Fackler will conduct a clinic on internal medicine. In the evening, the annual banquet of the association will be held. On June 12, Dr. Richard C. Cabot, Boston, will conduct a medical clinic, and Dr. Joseph Ransohoff, Cincinnati, one on surgery. All of these clinics will be held in the morning, and at the Cincinnati General Hospital. The afternoons will be devoted to clinics at the various local hospitals. The commencement exercises will be held on the morning of June 13 at the gymnasium of the university.

PENNSYLVANIA

Health Board Superseded.—The Chester Board of Health was abolished May 18, and the authority of the board transferred to the Department of Public Safety.

Gift to School Library.—The Phi Beta Pi Fraternity has presented the library of the School of Medicine of the University of Pittsburgh forty-five bound volumes of The Journal of the American Medical Association.

Quarantine Hospital Inadequate.—The State Economy and Efficiency Commission has inspected the Quarantine Hospital at Marcus Hook, and report it inadequate to meet the demands of the increased immigration at this point.

College of Physicians' Banquet.—The annual banquet of the College of Physicians of Pittsburgh was held at the Fort Pitt Hotel, May 27. The guests of honor were Dr. Noble W. Jones, Portland, Ore., who spoke on "Principles Underlying the Medical Treatment of Gastro-Intestinal Stasis"; Dr. Willia Garry Morgan, Washington, D. C., and Dr. John P. Sawyer, Cleveland, Ohio.

To Train Medical Missionaries.—The Pennsylvania Medical Missionary Society is now entering on the last year of its first quarter century. The objects of the society are to give assistance to students preparing for medical missionary work, and to arouse interest in medical missions; to establish and maintain homes for the use of missionaries or of students preparing for this work, and to obtain systematic contributions of money for these objects. The new Rest Home for missionaries at home on furlough, at Ventnor, was opened this month. The society is interdenominational in all its endeavors.

Philadelphia

Memoir to Dr George MacClellan.—A memoir of the late Dr. George MacClellan, founder of the Pennsylvania School of Anatomy and professor of artistic anatomy at the Academy of Fine Arts, was read May 28, at the meeting of the philobiblion Club, by Dr. J. Chalmers DaCosta.

Lebanon Hospital Opened.—The new Lebanon Hospital at 1728 N. Seventh St., was formally opened June 1. The new building has a capacity of thirty beds and has a well-equipped laboratory for microscopic and chemical examinations. The nurses' training school will be installed as well as a staff of six nurses.

Memorial Meeting for Dr. Moon.—A tribute to the late Dr. Robert C. Moon was paid, May 23, by an audience of largely sightless people, who crowded Witherspoon Hall. The father of the recently deceased physician had invented the Moon type system of reading for the blind and the son, an able ophthalmologist of Philadelphia, had also largely devoted his best energies to relieve these sufferers.

Personal.—Dr. James M. Anders has been appointed by Mayor Blankenburg, a member of the Board of Health to succeed Dr. Walter H. Andrus, who resigned several months ago.——Dr. S. W. Newmayer, head of the division of child hygiene, has been appointed assistant chief medical inspector in the Bureau of Health, to succeed Dr. Charles A. Groff, resigned.——Dr. Edward A. Leonard, Jr., has qualified for the position of assistant chief resident physician of the Bureau of Charities.

Plans Relief for Blockley.—To relieve overcrowding at Blockley, Director of Health and Charities Harte proposes to use at once a portion of the $60,000 available for a power plant in the new Home for the Indigent, at Holmesburg, in such a manner as to open the institution at an early date. With the installation of a temporary plant and the expenditure of possibly $15,000 on beds and other furnishings, 1,000 men from Blockley can be transferred to the new institution.

Agreement on Bodies.—The controversy between the coroner's office and the State Anatomical Board over the disposition of unclaimed bodies has been tentatively settled by an agreement to take the affair to court and abide by the decision. A test case will be made of the first unclaimed body that comes to the department. The state board made a concession in the case of bodies on which post-mortem examinations have been made, for in the past the board has refused to accept them.

Demonstration by State Board of Health.—The meeting of the Philadelphia County Medical Society on May 27 was devoted to an exposition of the work of the State Department of Health. Beginning at noon, there was an exhibit in Cadwalader Hall of relief maps, models and charts of the work of the department. Demonstrators were in attendance, and literature regarding the subjects was presented to each visitor. In the evening the topic announced was "An Evening by the Department of Health, Commonwealth of Pennsylvania." Dr. Samuel G. Dixon, state health officer, delivered an address, and others spoke on "Vital Statistics," "Medical Division," "County Medical Work," "Typhoid Fever," "Engineering Division," "Laboratories," "Dispensaries," "Sanatoria," "Philanthropic Cooperation in State Tuberculosis Work" and "Experiences as an Intern in a State Tuberculosis Camp."

For an Effective Housing Bureau.—Under the supreme court decree in the housing and sanitation suit that a new division of the Department of Health and Charities could be established only by the will of the councils irrespective of the act of assembly authorizing it, Dr. Richard H. Harte, director of health and charities, on May 25, reinstated the three heads of the old divisions deposed by Assistant Director Wilson several months ago. The men reinstated were the head of the division of sanitary inspection, head of the division of house drainage and head of the division of tenement house inspection. Dr. Harte has announced his determination to cooperate with councils in making the new division of housing and sanitation of the Department of Health and Charities, a most effective branch of the city government, and he will endeavor to prevail on councils to authorize the establishment of this new division and if councils are not willing to provide money for all the hundred inspectors authorized by the act of assembly, the department will do its best with the members of inspection the councils shall allow.

SOUTH DAKOTA

Personal.—Dr. Burtis T. Green, Brookings, sails for Europe June 13.

New Officers for State Association.—At the thirty-third annual meeting of the South Dakota State Medical Association held at Watertown, May 26-28, the following officers were elected for the ensuing year: president, Dr. Fred Treon, Chamberlain; vice-presidents, Drs. James B. Vaughan, Castlewood, and Francis M. Crain, Redfield; secretary-treasurer, Dr. Robert D. Alway, Aberdeen; delegate to American Medical Association, Dr. Edmund D. Putnam, Sioux Falls; alternate, Dr. Silas M. Hohf, Yankton. Sioux Falls was selected as the place of the next meeting.

WASHINGTON

Personal.—Dr. Irving Conditt, city physician of Seattle, has been appointed surgeon of the U. S. S. *McArthur*, engaged in coast and geodetic survey.

Rat-Proofing Ordinance.—The city council of Seattle has approved an ordinance, effective May 24, 1914, requiring the rat-proofing of all new buildings and buildings undergoing extensive repairs. The enforcement of the ordinance primarily devolves on the superintendent of buildings who will work in cooperation with the U. S. Public Health Service. Under date of May 26 the finding of a plague-infected rat was reported from Seattle.

GENERAL

Correction.—Dr. R. G. Hoskins calls attention to the fact that there is an inaccuracy in a statement made in his article, page 1803 of this issue, and that the statement beginning "Weed of Johns Hopkins has recently," etc., together with the reference should be deleted.

Military Surgeons Meeting.—The Association of Military Surgeons of the United States will hold its twenty-third annual meeting in Cincinnati, September 29-30 and October 1-2. Brigadier General Charles Adams, M. C., Ill. N. G. (retired), Chicago, is president of the association, and Dr. Charles A. Lee Reed, Cincinnati, is chairman of the committee on arrangements.

Bacteriological Standards for Milk.—*Public Health Reports*, May 15, contains a partial list of cities and towns in the United States of 10,000 population and over which have adopted a bacteriologic standard of purity for milk and cream. The total population of the cities included in the table given in the report is 21,043,325. The maximum number of bacteria allowed per cubic centimeter ranges from 1,500,000 for cream and 1,000,000 for raw milk, down to 10,000.

Gynecologists Elect Officers.—At the thirty-ninth annual meeting of the American Gynecological Society, held at Boston, May 19-21, the following officers were elected: president, Dr. Thomas J. Watkins, Chicago; vice-presidents, Drs. Frank F. Simpson, Pittsburgh, and Howard C. Taylor, New York City; secretary, Dr. Leroy Broun, New York City (reelected), and treasurer, Dr. J. Wesley Bovee, Washington, D. C. The place of meeting for next year was not decided.

American Pediatric Society Election.—At its twenty-sixth annual meeting held in Stockbridge, Mass., May 25-27, the following officers were elected: president, Dr. George N. Acker, Washington, D. C.; vice-president, Dr. Henry L. Coit, Newark, N. J.; secretary, Dr. Samuel S. Adams, Washington, D. C. (reelected); treasurer, Dr. Charles H. Dunn, Boston, Mass. (reelected); delegate to the Association of American Physicians, Dr. Abraham Jacobi, New York. The next meeting will be held in Cape May, May 25-27, 1915.

German Neurologist in America. — Professor Otfrid Foerster, neurologist of Breslau, Germany, is now visiting the United States. He was a guest of several Chicago physicians during the week of May 23-30, and has now gone to the Rocky Mountain states. Professor Foerster will speak in the Section on Nervous and Mental Diseases of the American Medical Association in Atlantic City, June 24, his subject being "The Borders of the Areas of Anesthesia, Analgesia and Thermo-Anesthesia in Lesions at the Different Levels of the Sensory Tract."

Physicians' Study Travels.—The first annual tour of the American Society of Physicians' Study Travels includes the cities and health resorts in and between Philadelphia, Canada and New England. The number is limited to 125 persons, and the tour will start from Philadelphia, June 26, immediately after the meeting of the American Medical Association in Atlantic City, and will return to Philadelphia July 16. The expense per individual, including all charges en route, will be $180. Those interested should communicate with the secretary, Dr. Albert Bernheim, 1225 Spruce Street, Philadelphia.

FOREIGN

Leprosy in Norway.—According to a table in Public Health Reports, May 29, from 1906 to 1910 the number of deaths from leprosy in Norway was 211. Of these 128 were males and 83 females. At the end of 1910 there were in that country 323 persons suffering from the disease, of whom 137 were males and 186 females.

Physicians in China.—In the part of China around the Shansi Mission of the American Board of Commissioners for Foreign Missions, there is a territory with only seven physicians to fourteen million people. There are many out-stations where patients are cared for, and several opium refuges are governed from Fenchow-fu. The board is continually calling for young physicians, but the response to the service has not been what it deserves.

Deaths in the Profession Abroad.—P. H. Eijkman, Scheveningen, the Netherlands, aged 51. Indefatigable in his efforts to promote international scientific intercourse, he founded in 1910 at the Hague the *Bureau préliminaire de la fondation pour l'internationalisme*. It listed then 192 different international organizations for medicine or the natural sciences.——I. Wickman, instructor in nervous diseases at the University of Stockholm and an early authority on poliomyelitis, aged 37.——D. Biondi, professor of surgery at the University of Siena.

Responsibility for Outer Garments Left in Waiting-Room.—The supreme court at Rome, Italy, recently decided a case on appeal in favor of a physician who was sued for damages as a patient's overcoat, left in the anteroom, had been stolen while he was with the doctor. The latter proved that the outer door was always locked and an attendant kept to open the door. He was considered to have thus acted "like a father" and the plaintiff's claim was not allowed. The judge emphasized that the responsibility of the physician in respect to office patients is not like that of a hotel-keeper for the belongings of his guests. The physician is responsible only *en bon père de famillie* for the outer garments, umbrellas and canes left in the anteroom to the office, and this responsibility does not extend to traveling bags. The *Semaine Médicale* in commenting on this case compares the codes of various countries, all sustaining the equity of the decision.

CANADA

Budget for Health Department.—The health committee of Winnipeg has asked an appropriation of $306,561.95 for the fiscal year. The chief items are for scavenger service, $140,064.40; salaries, $70,910.40; and operating and maintaining crematories, $67,627.15.

New Officers.—Toronto Academy of Medicine, May 5: president, Dr. Harry B. Anderson; secretary, Dr. Jabez H. Elliot.——Ontario Health Convention in Toronto, May 8: president, Dr. William R. Hall, Chatham; vice-president, Dr. Angus W. McPherson, Peterborough.

Provincial Association Meeting.—At the thirty-fourth annual meeting of the Ontario Medical Association, held in Toronto, the expected divulsion of the provincial from affiliation with the Canadian Medical Association was sidetracked, the matter being referred to a special committee of nine, including two who favored withdrawal, two who were satisfied with present conditions, and five members supposedly disinterested. The address in surgery was delivered by Dr. John M. T. Finney, Baltimore, on "The Cause of Failure in Operations for Choleliathisis"; that in obstetrics by Prof. B. P. Watson, Toronto, who gave a historical review of "Forceps, Their Proper Use, Etc."; and that in medicine by Dr. Emanuel Libman, New York City, on "Subacute Bacterial Endocarditis." The following officers were elected; president, Dr. David J. Gibb Wishart, Toronto; first vice-president, Dr. Adam T. Shillington, Ottawa; secretary, Dr.

Frederick A. Clarkson, Toronto, reelected; and treasurer, Dr. Jabez H. Elliott, Toronto, reelected.

CANAL ZONE

Treatment of Employees.—Circular 618, dated April 1, governs the treatment of employees in hospital and elsewhere. Employees will receive free treatment in the hospitals in case of injury or disease other than alcoholism or venereal disease. They will be admitted only on request of a physician of the health department or the head of a department or division to which the employee belongs. A charge of $1 for each visit will be made by each physician of the health department to an employee at his home or quarters, except that no charge will be made for the first visit if the employee is unable to go to the hospital or dispensary. Employees living with their families may be treated free at home or in quarters if, in the opinion of the physician, they cannot go to the dispensary or hospital. Employees treated in special wards shall be charged $1 a day and for a private room shall be charged $1.50 per day. Special nurses will be charged for at the rate of $3 per day and a special servant at $1. Members of the families of employees may consult free of charge any physician of the health department at the hospital or dispensary. Other regulations in regard to charges in hospital for employees on different rates of pay, for Army, Navy and marine services, for the diplomatic and consular corps and for the employees of contractors are also contained in the circular.

LONDON LETTER

London, May 22, 1914.

Deaths Due to Salvarsan

Although it is possible to administer salvarsan in a large number of cases without any ill results being observed, the occurrence of fatalities from time to time proves the truth of the saying of the leading French syphilographer, Gaucher, that it is "a treacherous remedy." All the explanations, brought forward one after another with no little ingenuity by Ehrlich and his followers, have broken down, and after much resistance the fact has to be admitted that under circumstances which are not understood, salvarsan may produce the nervous form of arsenical poisoning with fatal result. The contention that fatalities were due either to errors of technic or to administration in cases in which the drug was contraindicated by organic disease of the nervous or vascular system has been abundantly disproved. Most of the fatalities have occurred in young and vigorous patients, who, except for syphilis, were quite healthy. In England the number of reported deaths is small, but as in other countries, many are never published. A short time ago a man in Bradford suffering from anthrax was injected and died, as was admitted at the inquest, from arsenical poisoning. Two other deaths have recently been reported. In one a debilitated man aged 25, a subject of syphilitic ulceration of the palate and larynx, was treated in Dublin. The heart and kidneys were apparently normal. An intravenous injection of 0.4 gm. of salvarsan was followed by two rigors and vomiting. After recovering from these symptoms he collapsed and died twenty-five hours after the injection. At the necropsy the heart and kidneys were found normal. In the other case, a young man, aged 23, in the secondary stage of syphilis and otherwise apparently healthy, received an intravenous injection of 0.6 gm. at St. Mary's Hospital and the same dose a fortnight later at Guy's Hospital. Three days after the second injection coma and convulsions occurred and the patient died. The necropsy showed visceral hemorrhages and hyperemia of the brain. The heart, liver and kidneys were normal. At the inquest Dr. Womack, the pathologist, gave evidence that death was due to acute arsenical poisoning in a person with idiosyncrasy to salvarsan. He referred to the case of an American who died in London after a second injection under similar circumstances. Another case of the same kind has occurred in Manchester. Ehrlich's attention having been called to the fatality at Guy's Hospital, he wrote a letter to the *British Medical Journal* stating that he associates the nervous phenomena after salvarsan injection, particularly hemorrhagic encephalitis, with the destruction of spirochetes in the capillaries of the brain and the liberation of the endotoxins. The vascular system, altered by the endotoxins, is not oversensitive to salvarsan as such, for otherwise the symptoms would appear immediately after the second injection instead of two days later. The delay indicates that a derivative of salvarsan has come into action which he believes is an oxidation product. A third factor which also comes into play is a deficiency of epinephrin, favoring dilatation of vessels. He therefore suggests that epinephrin may be of use in overcoming "this scourge of salvarsan therapy." To this complicated explanation the reply may be made that it is almost entirely hypothetic and not sustained by evidence. Moreover, if it be true that salvarsan causes a dangerous liberation of endotoxin, this is surely an argument against its use. But that the symptoms are due to arsenical poisoning, pure and simple, is shown by their occurrence when salvarsan is administered in other diseases than syphilis and by their occurrence in patients who, having suffered from the disease and free from all manifestation of it, have shown toxic symptoms after injections administered as a precautionary measure. The profession seems to be so hypnotized by the well-earned reputation of a great pathologist as to be incapable of grasping the obvious with regard to these salvarsan fatalities.

PARIS LETTER

Paris, May 15, 1914.

Personal

May 12, the Académie de médecine elected two national associate members, Dr. Jules Boeckel of Strassburg and Dr. Albert Calmette of Lille (The Journal, May 2, 1914, p. 1414). Mention of Dr. Jules Boeckel was made recently on the occasion of his departure from the civil hospital of Strassburg and his nomination as honorary member of the Société de chirurgie de Paris. Dr. Albert Calmette, who was born at Nice in 1863, when colonial and marine physician in 1890, founded at Saigon the first Pasteur institute outside of France. After his return to France, he became one of the most valued pupils of Pasteur, who in 1895 entrusted him with the task of organizing the institute of Lille, which he continues to direct. He has particularly studied the problems of plague and snake-poison serotherapy. He has given particular attention to the study of tuberculosis and has introduced antituberculosis dispensaries, which are generally preferred in France to tuberculosis sanatoriums.

Has a Military Officer the Right to Operate?

The very important question of unauthorized practice of surgery by military officers is now receiving the attention of the medical profession. In some of the frontier military posts of our colonies, there are no military physicians. The heads of such posts have been instructed by physicians in the elements of hygiene and medicine but not in surgery. In serious cases, sick or wounded men have been transported with all possible care to the nearest military infirmary or hospital. This prudent caution was not observed in a recent case. Dr. Granjux reports that in a post of southern Algeria, an officer amputated the leg of a seriously wounded brigadier. The fact was reported to the minister of war, who sent to the commander of the army corps a letter of congratulations in which he requested him to invite the director of the service of hygiene to prepare for the use of the southern posts a notice pointing out the superiority of conservative surgery and the means of practicing it even under unfavorable circumstances, thereby permitting the patient to await the arrival of a physician and avoid amputation. Dr. Granjux points out the great danger of such operations made by officers who have the best intentions, but necessarily lack the requisite skill, and observes that the minister of war, while ostensibly congratulating the amateur surgeon, conveys an implied reproof which is not made direct for fear of making trouble for him and for the government.

Nurses and Antityphoid Vaccination

An odd conflict has just arisen between the administration of the Public Charities and the nurses. The Public Charities has recently decided to vaccinate its nurses with the serums of Vincent or Chantemesse. The nurses' union (*syndicat*) has protested against the use of these serums, which it says have killed several nurses. The *syndicat* declares that the serum caused the death of two female nurses, one at the Beaujon Hospital and the other at the Necker Hospital, and that two other female nurses, one at the Lariboisière and the other at the Charité, have been made seriously ill. M. Mesureur, director of the Public Charities, replies that the deaths attributed to the antityphoid serum are really not due to the vaccination. The nurse at the Beaujon Hospital had received two inoculations and was not protected. She died of typhoid fever, which broke out a month after the last inoculation. The nurse at the Necker Hospital died also of typhoid fever, during the course of which three therapeutic injections had been made. The case, therefore, has no bearing on preventive vaccination.

BERLIN LETTER

Berlin, May 15, 1914

Annual Meeting of the German Surgical Society

(*Continued from page 1674*)

THYROID TRANSPLANTATION

Kocher of Bern reported the permanent results of thyroid transplantation in man. In animal experiments it was possible to transplant the thyroid gland and its vessels, but only in case of autotransplantation, which is of no significance for the present question. No success has hitherto been obtained by means of homotransplantation. Probably the question also will be solved by some method of weakening the immunity of the recipient and increasing the vigor of the transplant. For the prevention of tetany, when it was not possible at the operation to preserve the epithelial bodies, Kocher immediately reimplanted these. Also for the prevention of cachexia strumipriva, when for any reason the entire thyroid had to be removed, he reimplanted a portion of the healthy tissue. In cases of cretinism, in which the patient's own thyroid is not available, the attempt must be made, if necessary, to obtain material from relatives. The successful cases which Kocher has to show have not been controlled by histologic examination because he does not regard himself as justified in removing again a gland that has once been implanted.

He plants the graft in the bone-marrow, the peritoneal cavity, the preperitoneal tissue, the omentum or, following the method of Payr, in the spleen, which seems to him especially suitable for the purpose. In ninety-three cases he had eighteen favorable results; some of the patients had previously been taking thyroid preparations internally. It should be noted further that there are cases in which these preparations are tolerated only after a thyroid-grafting operation. In cases of cretinism, he had good results in twenty-one cases. For transplantation, he prefers the thyroid from a patient with exophthalmic goiter which is in the stage of hyperthyroidism. For good results, a single transplantation is not sufficient; new material must constantly be supplied either by the administration of thyroid preparations or by multiple transplantations. In cretins, moreover, preliminary long-continued administration of the thyroid is necessary for success with the transplantation.

Eiselsberg of Vienna reported a case of myxedema in which an improvement was secured by repeated transplantation; but after a certain interval a new transplantation always became necessary. He has succeeded in transplanting the epithelial bodies but with only a temporary effect.

In a case of congenital lack of the thyroid, with complete idiocy, which Payr of Leipsic reported, an astonishing and unprecedented improvement lasting for two years and four months was achieved by transplanting a large piece of the mother's thyroid; but later a complete retrogression occurred. Three other transplantations gave satisfactory results. Payr said that in cases of acquired imperfect function of the thyroid, after failure of thyroid treatment, transplantation may be undertaken with good prospects of success. The causes for failure of transplantation in congenital cretins are partly the severe disturbances of development in the infantile brain which are present at the same time and partly the necessity of taking the graft from another individual. For an early diagnosis, Payr recommends a small exploratory incision in the neck. In this place, then, the transplant itself may be inserted or it may be embedded in the capsule of the thymus. There are many differences between the mode of action of transplanted thyroid tissue and thyroid treatment with the dried gland.

Stieda reported three cases of pronounced myxedema with more or less evident idiocy, in an 8-year-old boy, his sister of 7 and an 8-year-old girl. After the implantation of thyroid tissue, a pronounced improvement was evident in all three cases. At first it showed rapid progress and then became stationary. A disappearance of the myxedematous changes in the skin could be demonstrated as well as a growth in height and an evident increase in intelligence. Two of the children are still under observation, but the third died nearly four years later, after an operation for tuberculosis. At the necropsy this case, which had been especially improved, showed that microscopically the thyroid tissue implanted in the head of the tibia was no longer recognizable but, on the other hand, a small thyroid gland was found which had escaped discovery during life. Aside from the grafting operation, the children received no other treatment.

Schaack of St. Petersburg has repeatedly undertaken the implantation of the thyroid in the bone-marrow or in the subcutaneous adipose tissue and has seen improvement which, as a rule, however, lasted only two months. He has never observed a permanent cure.

Müller of Rostock implanted the thyroid in the bone-marrow of the tibia in one cretin, with merely temporary improvement. He later opened up the tibia again but found nothing left of the thyroid gland except a few isolated cells.

Enderlen of Wurzburg stated his conviction based on wide experience that the thyroid implanted in this way will not long maintain its life.

THYROID CYSTS

Riedel of Jena reported on the dangers and disturbances from cysts of the thyroid. Of 1,070 patients with goiter who were operated on, 148 had large isolated cysts. The latter often develop even in childhood and sometimes hinder the growth of the trachea to a remarkable degree (11 cases), and relatively often sink down behind the first rib or the sternum (21 cases). Exophthalmic goiter seldom occurs in a thyroid with cysts (6 cases); hyperthyroidism is more frequent (12 cases). If such patients are operated on under general anesthesia, the pulse in some instances sinks to the normal and remains thereafter slow; in others it becomes rapid again after subsidence of the anesthesia and the same symptom is seen in solid goiter with exophthalmic goiter.

In these cases there is a paralysis of the subcortical center of the sympathetic in the subthalamic region which, in turn, has relations with the posterior part of the frontal lobe of the brain. This center, that in exophthalmic goiter or in hyperthyroidism is primarily or secondarily stimulated, is paralyzed by chloroform. The primary factor of exophthalmic goiter, however, is often the disease of the thyroid shown by the morbid anatomy. If the greater part of the thyroid is removed by an early operation, the exophthalmic goiter also rapidly disappears. If the thyroid grows again, the exophthalmic goiter immediately returns, but it disappears again as soon as the newly grown thyroid is removed, even if it is only very small, for it requires the influx of only a minute amount of the juice of the thyroid into the blood to stimulate the sympathetic center. In chronic cases this center remains irritated for a long time, even for years, in spite of the removal of the greater part of the goiter or the thyroid cysts.

Effusions of blood easily occur into thyroid cysts, and still more frequently inflammatory changes occur (mostly circumscribed and harmless). Of three women with subacute attacks, two died of pericarditis or endocarditis, and one of pneumonia, although pus was found in the cysts in only one of the cases and serum in two. In one patient the inflamed cyst was probably tuberculous. Malignant degeneration of the cysts is very unfortunate. In two cases, carcinoma of the esophagus developed opposite old, hard, calcified substernal cysts, so that a causal connection between the two must be considered. Tough-walled cysts permit easy enucleation; sometimes a severe hemorrhage from the thyroid tissue, especially from the capsule, necessitates the almost complete removal of that half of the goiter. For the extirpation of the subcostal cysts, a long curved incision is necessary; the goiter separated at the isthmus must be loosened from the trachea and also higher up and so made movable, and then the subcostal tumor can easily be pushed up and drawn out of the chest. An enucleation of a subcostal cyst is dangerous on account of possible hemorrhage. The capsule of the goiter should be removed with it.

THE THYMUS AS A FACTOR IN EXOPHTHALMIC GOITER

Von Haberer of Innsbruck communicated his results from thymectomy in exophthalmic goiter and goiter. He has now a record of sixteen cases of resection of the thymus. In fourteen cases the thyroid and the thymus were both removed; in two cases the thymus alone was removed, and one patient was cured. In eight cases there was exophthalmic goiter with hyperplasia of the thymus, while in seven there was simple goiter. The question whether in certain cases the thymus and in others the thyroid should be attacked operatively, has not yet been settled. There are severe cases of exophthalmic goiter without hyperplasia of the thymus. Still, he believes that in all cases of exophthalmic goiter and goiter one should determine whether or not the thymus is unduly large and remove it in case of hyperplasia.

According to Albert Kocher of Bern, the experience in Bern is not the same. A participation of the thymus was found only in very rare cases. If it was discovered at operation its removal did not seem to be indicated, according to the experience there, as very frequently, after the removal of the thyroid, the thymus became reduced in size. The hyperplasia of the thymus seemed to Kocher to be a regional and familial affection. He called attention further to the connection between hyperplasia of the thymus and hypoplasia of the adrenals. In two cases of thymectomy one patient was cured.

In the discussion Klose of Frankfort referred the contradiction in the experience of the two previous speakers and himself to regional conditions, and briefly described his observations.

Schloffer of Prague regards thymectomy as not always a very easy operation. In one of his cases it proved peculiarly complicated. In conclusion, von Haberer gave his opinion that thymectomy in case of hyperplasia of the thymus presented no difficulties.

PUNCTURE OF THE CORPUS CALLOSUM

Stieda reported the results which had been obtained at the Halle clinic with puncture of the corpus callosum in genuine epilepsy and idiocy. One case of jacksonian epilepsy with a congested papilla was of special interest in that the attacks gradually ceased completely with no further signs of choked disk to date after four and one-half years, while in most cases of epilepsy there is only a temporary cessation but a decided weakening of the attacks.

An earlier operation will surely give better results, as the puncture of the corpus callosum is a minor operation, quickly made and not dangerous. It can be done without injuring the brain and without shock, and under local anesthesia. In comparison with the other methods of operating for genuine epilepsy, puncture of the corpus callosum is not only a competitor but probably deserves preference.

Hildebrand of Berlin has performed puncture of the corpus callosum twice and was not very much pleased with the results. He does not regard the operation as so very insignificant, as it is easy to injure a vein and produce dangerous bleeding.

Tilmann of Cologne in case of epilepsy first determines by a lumbar puncture whether there is increased pressure. If positive, he makes a puncture of the ventricle; if he also finds here an increased pressure, he punctures the corpus callosum.

Lossen of Cologne applied puncture of the corpus callosum in three cases of hydrocephalus without results. In his opinion, the operation must be made in several places in order to secure success. He recommends puncture of the cisterna magna, but in addition he makes a puncture of the corpus callosum and of the ventricle.

Schloffer of Prague has performed puncture of the corpus callosum about twenty times and observed a temporary unilateral paralysis following it in one case.

DEEP INJECTIONS OF ALCOHOL FOR NEURALGIA

Härtel has treated twenty-seven cases of trigeminus neuralgia according to his method with injections of alcohol into the gasserian ganglion with immediate relief in every instance with the exception of three hysterics. In relapses freedom from pain could always be secured again by repeating the injection. The method is superior to all operative and conservative peripheral methods and is calculated materially to reduce the number of intracranial operations.

GANGLIECTOMY FOR OCCIPITAL NEURALGIA

Oehlecker of Hamburg-Eppendorf reported on a new operation in the field of nervous diseases, namely, the extirpation of the second spinal ganglion in certain forms of occipital neuralgia. One patient had unbearable neuralgia recurring after a peripheral operation on the occipitalis major nerve and was completely cured by Oehlecker's operation. In another, the occipital neuralgia developed after injury of the anterior branch of the third cervical nerve, and the occipitalis major was extirpated together with the ganglion. The same operation was performed on a third patient in whose case it was assumed that the cause of the neuralgia, which came on after an operation for carcinoma of the tonsil and base of the tongue, was more centrally situated.

SURGICAL MEASURES IN PULMONARY TUBERCULOSIS

Friedrich of Königsberg reported on the systematic surgical treatment of pulmonary tuberculosis by removal of ribs and induced operative paralysis of the diaphragm, etc., by cutting the phrenic and intercostal nerves. The performance of the operation in two stages, the use of local anesthesia and the limitation of the extent of the resections in suitable cases have gradually led to the extension of the indications even to cases of medium severity. He was not ready to give a final judgment on this operative paralysis of the phrenic nerve, but he took a very conservative and skeptical position.

Sauerbruch of Zurich described the indications for operative treatment. Fresh incipient cases are not suited for operation. Those cases, however, in which an active progressive process is present in both lungs are to be excluded. The cases best suited to the operation are those of a fibrous character. Of 122 patients operated on by an extrapleural plastic operation, 2 have died, 27 have grown worse, 65 remarkably improved and 24 are cured. One can speak of an actual cure only after the lapse of two years. Sauerbruch applies the same method of operation as Friedrich and is, in general, an opponent of using a filling.

Wilms of Heidelberg considers the use of a filling under definite indications as justified and curative. In addition to this, he is applying resection more and more. He has operated in 21 cases, with 1 death as a result of the operation and 2 occurring later. Four patients are cured, 7 remarkably improved and 5 others improved. His *Pfeilerresektion* technic cuts the ribs close to the spine and sternum.

BUDAPEST LETTER

Budapest, May 4, 1914.

Birth and Death Statistics of Europe

The *Hungarian Statistical Bureau publishes the following data of the population movement of Europe from 1902 to 1911.* The increase of population in percentage is as follows:

	Per Cent.
Russia	18.81
Servia	15.83
Roumania	14.38
Bulgaria	14.12
Germany	13.64
Holland	12.79
Switzerland	11.65
Denmark	9.52
Belgium	8.61
England	8.30
Austria-Hungary	7.78
Sweden	6.99
Norway	6.69
Italy	6.05
Portugal	5.90
Spain	4.70
France	1.42

According to these statistics the Slavs themselves rank foremost and the Slavonic nations occupy the second place. From a geographic point of view the Balkan people are first, while the so-called *Kulturstaaten* (cultured nations) which lead in art, technical sciences, politics, etc., rank last.

The mortality statistics show quite a different picture. Here, naturally enough, the cultured states rank first. Taking ten thousand inhabitants as a basis, the rate of mortality from 1902 to 1912 is as follows:

Russia	298
Roumania	256
Hungary	294
Servia	236
Austria	232
Bulgaria	231
Spain	224
Italy	215
France	193
Germany	184
Finland	178
Ireland	173
Belgium	164
Scotland	163
England	152
Switzerland	150
Holland	149
Sweden	147
Norway	140
Denmark	140

Damages Paid by An Insurance Company to a Doctor for Libel

A well-known foreign insurance company working in Hungary circulated a letter to all the insurance companies with the information that it had withdrawn its confidence from a certain doctor, because his urine examinations were unreliable. As the doctor in question had been the medical adviser for several insurance companies, a large part of his livelihood has been derived from the examination fees, and considerable material loss was involved. On inquiry for the reason of his dismissal, the letters from the directors, containing instructions to dismiss him because he was an "unreliable doctor" were shown to him. The doctor sought the advice of the medical association, and was advised to sue the company for libel and damages. The question of libel has not been decided, as yet, but damages of $2,000 (10,000 kronen) have already been awarded him.

Marriages

James Lyman Whitney, M.D., San Francisco, to Miss Elizabeth Goodrich of Saratoga, Cal., May 14.

Joseph H. Williams, M.D., Webster Groves, Mo., to Miss Maud North of Gray Summit, Mo., May 28.

Robert Clayton Thackeray, M.D., Racine, Wis., to Miss Marion Browne, at Evanston, Ill., May 16.

George Washington Gault, M.D., to Miss Mabel E. Sellers, both of Marysville, Pa., May 1.

Louis K. Guggenheim, M.D., to Miss Maude Hellman, both of St. Louis, May 21.

Deaths

Ferdinand Eugene Daniel, M.D. editor of the *"Red Back" Texas Medical Journal;* and one of the best-known practitioners of the Southwest; died at his home in Austin, Tex., May 14, aged 74. He was born in Hicksford, Va., July 18, 1839, and was graduated from the New Orleans School of Medicine in 1862. Before his graduation, he had been a private of the line in the confederate service, and immediately after his graduation he reentered the service as surgeon. He also served during 1863 as Judge Advocate with the Army of the Tennessee, as secretary of the Army Board of Medical Examiners in General Bragg's division; and also on the staff of Lieut. Gen. Hardee. He was for many years a member of the State Medical Association of Texas, and was its first president in 1904, under the reorganization. Dr. Daniel was one of the founders of the first Texas medical college and a member of its faculty in 1867 and 1868. He founded the *Texas Courier Record of Medicine*, and established the *"Red Back" Texas Medical Journal* in 1885. Dr. Daniel was widely known as a writer, not only of polemics, but on scientific subjects.

James Gillespie Hunt, M.D. Jefferson Medical College, 1871; a member of the Medical Society of the State of New York; formerly president of the Northern Branch of the New York State Medical Association and Oneida County Medical Society; five years commissioner of the State Board of Health; local surgeon to the New York, Ontario and Western; Delaware, Lackawanna and Western, and West Shore Railways; a member of the staff of the Faxton Hospital, Utica, N. Y.; for three terms coroner of Oneida County; and for twenty years health officer of Utica; formerly assistant surgeon to the Forty-Fourth Separate Company, N. G., S. N. Y.; died at his home, May 17, from cerebral hemorrhage, aged 68.

John E. Brady, M.D. University of Buffalo, N. Y., 1860; a Fellow of the American Medical Association since 1866; a charter member of the Michigan State Medical Society; and for some time president of the Grand Rapids Medical and Surgical Society; coroner of Kent County, Mich., for several terms; surgeon to Butterworth and the Union Benevolent Association hospitals, Grand Rapids; formerly professor of physical diagnosis, and diseases of the chest, heart and lungs in Grand Rapids Medical College; assistant surgeon of the Forty-Fifth Illinois Volunteer Infantry during the Civil War; died at his home in Grand Rapids, May 18, aged 77.

James McDonald Keller, M.D. University of Louisville, Ky., 1852; medical director in the confederate service throughout the Civil War; once professor in Louisville Medical College and Kentucky School of Medicine, president of the Board of Education of Louisville, and president of the Kentucky State Medical Association; for forty years a practitioner of Hot Springs, Ark.; at one time president of the Arkansas Medical Society, and an honorary member of the Hot Springs-Garland County Medical Society; died at his home in Hot Springs, May 27, aged 82.

Edward Marsh, M.D. Bellevue Hospital Medical College, 1875; of Esperance, N. Y.; a member of the Medical Society of the State of New York; and one of the best-known practitioners of the Schoharie Valley; was struck by a freight train at Central Bridge, N. Y., May 19, and died from his injuries a few hours later in St. Peter's Hospital, Albany, aged 60.

John P. Webster, M.D. Hahnemann Medical College, Chicago, 1883; Harvey Medical College, Chicago, 1896; a Fellow of the American Medical Association; a member of the Mississippi Valley Medical Association, American Association of Railway Surgeons, and Erie Railroad Surgeons' Association; chief surgeon of the Chicago and Western Indiana Railway; local surgeon to the Erie and Monon systems; surgeon to the Englewood Hospital and St. Ann's Hospital Sanatorium; died at his winter home in Pasadena, Cal., May 24, aged 62.

Joseph Edouard Adolphe Lanouette, M.D. University of Bishop's College, Montreal, 1872; a member of the New Hampshire Medical Society and American Public Health Association; formerly president of the Manchester, N. H., Board of Health; and of the New Hampshire State French Medical Society; consulting surgeon to Sacred Heart Hospital, Manchester; surgeon of the Ninety-Second Battalion, Canadian Militia, from 1873 to 1881; died at his home in Manchester, May 16, from cerebral hemorrhage, aged 64.

Christopher Hamilton Tebault, M.D. Tulane University, New Orleans, 1862; surgeon of the Twenty-First Louisiana and Tenth South Carolina Infantry, C. S. A., during the Civil War; for two years teacher of anatomy in his Alma Mater; a member of the staff of Charity Hospital, New Orleans, for many years; surgeon-general of the United Confederate Veterans, for twenty-five years; one of the best-known practitioners of New Orleans; died at his home in that city, May 24, aged 74.

Brooks Ford Beebe, M.D. Medical College of Ohio, Cincinnati, 1880; a Fellow of the American Medical Association; a member of the Cincinnati Academy of Medicine, American Medical-Psychological Association, Mississippi Valley Medical Association and Ohio Valley Medical Society; for many years professor of mental diseases in his Alma Mater; died at his home in Cincinnati, May 29, from cerebral hemorrhage, aged 63.

John Forrest Dillon, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1850; who, after six months of practice, took up the study of law, and was judge of the seventh judicial district, and later a justice of the supreme court, New York; and professor of real estate and equity jurisprudence in Columbia University; died at the home of his daughter-in-law in New York City, May 5, aged 82.

William James Dugan, M.D. Jefferson Medical College, 1896; a member of the Medical Society of the State of Pennsylvania; professor of electrotherapeutics in his Alma Mater, and consulting neurologist to the Jefferson Hospital; bacteriologist to the Maigner Laboratory of Original Research, and Pepper Laboratory of the University of Pennsylvania; died at his home in Philadelphia, May 20, aged 45.

Murdoch Alexander Lindsay, M.D. University of Edinburgh, Scotland, 1908; professor of pathology and bacteriology in Dalhousie University, Halifax, N. S.; a pathologist in the employ of the Nova Scotian government; was one of the passengers lost by the sinking of the steamer *Empress of Ireland*, after collision in the St. Lawrence River, May 29.

John William Dowling, M.D. New York Homeopathic Medical College New York City, 1886; professor of medicine and secretary of the faculty of his Alma Mater; attending physician to the Flower Hospital, New York City; died in Middletown, N. Y., May 11, from cerebral hemorrhage, aged 49.

Jephtha C. Clark, M.D. New York Homeopathic Medical College, New York City, 1885; for twenty-seven years a practitioner of Andover, N. J.; for several years a member of the Board of Education, and coroner of Sussex County; died at his home, May 16, from cerebral hemorrhage, aged 54.

Louis Hartnagel Redon, M.D. McGill University, Montreal, 1901; of Seattle, Wash.; a Fellow of the American Medical Association, aged 37; who was found unconscious, in an alley, May 10, having apparently been injured by an automobile; died in a hospital in Seattle, May 11.

William Edward Sullivan, M.D. University of Michigan, Ann Arbor, 1912; aged 36; a member of the Louisiana State Medical Association; and a practitioner of Monroe; died in that city, May 21, from the result of injuries received when his automobile ran into the Ouachita River.

William E. Reed, M.D. College of Physicians and Surgeons, St. Joseph, Mo., 1881; for more than thirty years a practitioner of Los Angeles, Cal.; died at his home in that city, April 17, aged 67.

William C. Henry, M.D. Miami Medical College, Cincinnati, 1870; a member of the Indiana State Medical Association; and a charter member and first president of the Dearborn County Medical Society; surgeon of the Eighty-Third Indiana Volunteer Infantry during the Civil War; died at his home in Aurora, Ind., about May 20, aged 73.

Robert Bailey Nelson, M.D. Vanderbilt University, Nashville, Tenn., 1903; a member of the Tennessee State Medical Association; of Memphis; aged 33; who was injured in a collision between his automobile and a railway train near Memphis, April 15; died from the results of his injuries at the Gartly-Ramsay Hospital, Memphis, May 12.

Howard B. Gates, M.D. New York Homeopathic Medical College, New York City, 1885; a Fellow of the American Medical Association; for many years superintendent of the San Jose, (Cal.) County Hospital; and later a surgeon of Los Angeles; died in Rome, Italy, May 9, from peripheral neuritis, aged 46.

George William Goetz, M.D. University of Louisville, Ky., 1910; of McKeesport, Pa.; was found dead on the railway tracks near Hawkins Station, Pa., May 12, aged 28. It is believed that Dr. Goetz was murdered and robbed and his body thrown on the tracks to conceal the evidence of the crime.

Philip B. Housekeeper, M.D. Jefferson Medical College, 1868; a member of the Medical and Chirurgical Faculty of Maryland; and physician to the Cecil County, Md., almshouse and insane hospital; died at his home in North East, Md., May 17, from heart disease, aged 68.

Charles Frederic Wainright, M.D. Bellevue Hospital College, 1889; of New York City; from 1880 to 1902, professor of internal medicine and dean of the University Medical College, Kansas City, Mo.; died at his home in Englewood, N.J., May 7, from heart disease, aged 55.

William M. S. Curtiss, M.D. Baltimore University, 1893; a member of the Connecticut State Medical Society; in 1900 a representative from Cornwall in the General Assembly; died at his home in Bristol, Conn., May 17, from nephritis, complicated by pleurisy, aged 43.

Mason Volney Hunt, M.D. Medical College of Ohio, Cincinnati, 1874; medical director of the Liberal Life Insurance Company of Indiana, Anderson; and a member of the staff of St. John's Hospital, died at his home in Anderson, May 18, from heart disease, aged 65.

Daniel Morris Woolley, M.D. New York University, New York City, 1885; of Brooklyn; a specialist on diseases of the nose and throat; a member of the staff of King's County Hospital; died in a sanatorium in Flatbush, May 18, from carcinoma of the liver, aged 64.

William Shepard, M.D. Eclectic Medical Institute, Cincinnati, 1853; one of the founders of the Shepard Sanatorium; once a member of the legislature from Franklin County, Ohio; died at his home in Shepard, Ohio, May 15, from arteriosclerosis, aged 88.

William Crutcher, M.D. Jefferson Medical College, 1896; a Fellow of the American Medical Association; and a member of the first state board of medical examiners of Arkansas; died at his home in Pine Bluff, Ark., May 22, from pulmonary tuberculosis, aged 47.

Charles Hemsted Burbeck, M.D. Albany, N. Y., Medical College, 1859; a Fellow of the American Medical Association; a surgeon of volunteers during the Civil War; and a veteran physician of Troy, N. Y.; died at his home in that city, May 9, from pneumonia, aged 77.

Otis H. Babbitt, M.D. New York Homeopathic Medical College, New York City, 1882; a Fellow of the American Medical Association; for several years physician to the Cayuga County Jail; died at his home in Auburn, N. Y., May 8, aged 60.

James Hervey Neagle, M.D. Louisville, Ky., Medical College, 1876; a Confederate veteran, and for many years a practitioner of Portland, Ore., and Seattle, Wash.; died at his home in Seattle, May 8, from nervous breakdown, aged 70.

Henry Herbert Lee, M.D. University of Vermont, Burlington, 1881; a member of the Vermont State Medical Society; died at his home in Wells River, early in April, from carcinoma of the pancreas, aged 56.

James Alexander Ashbaugh, M.D. Trinity Medical College, Toronto, 1891; for eleven years medical health officer of Windsor, Ont.; died in the Guelph (Ont.) Sanitarium, May 10, aged 41.

Christopher John Miller, M.D. Western Reserve University, Cleveland, Ohio, 1864; for many years a practitioner of Mansfield and Richmond County, Ohio; died in the Odd Fellows' Home of Ohio, Springfield, Ohio, March 6, from senile debility, aged 80.

James D. Whitney, M.D. Cooper Medical College, San Francisco, 1863; for many years a practitioner of San Francisco, and at one time a member of the staff of Governor Waterman; died in the Vendome Hotel, San Jose, Cal., May 9.

Horatio S. Brewer, M.D. Bennett Medical College, Chicago, 1879; for twenty-five years a member of the staff of the Chicago, Milwaukee and St. Paul Railway; a veteran of the Civil War; died at his home in Chicago, May 18, aged 68.

Carl D. S. Fruh, M.D. Jefferson Medical College, 1885; at one time demonstrator of anatomy in his Alma Mater; for nearly forty years a druggist of Philadelphia; died at his home, May 13, from nephritis, aged 64.

John Brelsford House, M.D. Vanderbilt University, Nashville, Tenn., 1894; for several years health officer of Allen County, Ky.; died at his home in Scottsville, May 8, from cerebral hemorrhage, aged 49.

George Ralph Bugbee, M.D. Dartmouth Medical School, Hanover, N. H., 1872; a member of the State Medical Society of Wisconsin; died at his home in Wausau, Wis., May 14, from heart disease, aged 65.

Frank Henry Nettles, M.D. Washington University, St. Louis, 1905; a member of the Missouri State Medical Association; died at his home in Cape Girardeau, Mo., May 11, from nephritis, aged 41.

Sharon Peter Heilman, M.D. University of Pennsylvania, Philadelphia, 1900; formerly of Kittanning, Pa.; and surgeon of the Kittanning Plate Glass Company; died in Phoenix, Ariz., May 11, aged 40.

William Elmore Barr, M.D. Ohio Medical University, Columbus, 1902; formerly of London, Ohio; died at the home of his father-in-law in Columbus, Ohio, May 8, from tuberculosis, aged 36.

Lafayette Stuck, M.D. University of Michigan, Ann Arbor, 1877; for thirty-five years a practitioner of Allegan, Mich., died at his home in that city, May 13, from cerebral hemorrhage, aged 66.

Ohan Gaidzakian, M.D. University of Vermont, Burlington, 1883; also a clergyman; formerly of Boston, Mass.; died in a sanitarium at Harmon-on-the-Hudson, N. Y., recently, aged 76.

Elmer Bertly Eddy, M.D. College of Physicians and Surgeons in the City of New York, 1873; of Providence, R. I.; died at the home of his daughter in that city, May 6, aged 65.

John H. Mathieson, M.D. McGill University, Montreal, 1871; formerly a member of the Board of Aldermen of St. Mary's, Ont.; died at his home in that place, May 10, aged 70.

Julius Benson Evans, M.D. Medical College of Fort Wayne (Ind.) 1880; a veteran of the Civil War; died at his home in Ada, Ohio, February 21, aged 70.

Felix Bernard Bramlette, M.D. University of Texas, Galveston, 1908; formerly of Greenville, Texas; died at his home in Austin, Texas, May 9, aged 30.

Omar Pasha Huston, M.D. University of Michigan, Ann Arbor, 1878; fell from a loft in his barn near Coweta, Okla., May 7, and was instantly killed.

Edwin E. Williams (license, Ill., 1893); a practitioner of Streator, Ill., for fifty-one years; died at his home, May 13, from chronic nephritis, aged 77.

Samuel B. Wright, M.D. University of Nashville, Tenn., 1875; died at his home in Stanford, Ill., May 13, from carcinoma of the throat, aged 63.

Nicholson C. Washington, M.D. Washington University, St. Louis, 1867; a Confederate veteran; died at his home in St. Louis, May 6, aged 70.

R. Pinkney Blackistone, M.D. University of Maryland, Baltimore, 1849; died at his home in River Springs, Md., recently, aged 91.

T. G. Butler, M.D. Medical College of Georgia, Augusta, 1860; of Malvern, Ark.; died at Pine Bluff, Ark., April 25, aged 84.

George W. Campbell, M.D. Jefferson Medical College, 1879; died at his home in Newport, Pa., May 5, aged 68.

D. C. Reese (license, Mo., 1883), died at his home in La Belle, Mo., April 26.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

GLYCO-HEROIN, SMITH

Report of the Council on Pharmacy and Chemistry

The following report was submitted to the Council by a referee and publication authorized.

W. A. Puckner, Secretary.

Glyco-Heroin Smith is marketed in a showy "patent-medicine" type of package, the label on which announces the presence of ½ grain of heroin to the fluidounce and admits the presence of 35 per cent. alcohol, an active ingredient that is not discussed in any way in the literature sent out by the manufacturer.

The composition of Glyco-Heroin Smith is given as follows: "Each teaspoonful represents: Heroin 1/16 grain. White Pine Bark 3½ grains. Ammonium Hypophosphite 3 grains, Balsam Tolu ¼ grain. Hyoscyamus 1 grain. Glycerin Q. S." The alcohol is not mentioned in the formula.

The advertising matter says of the merits of the formula:

> "Despite the fact that heroin, which is universally recognized as an invaluable respiratory sedative, is a conspicuous element of Glyco-Heroin, Smith, the other constituents, henbane, ammonium hypophosphite, balsam tolu and white pine bark are factors of no less importance; indeed, it is through the concerted action of its several ingredients that the preparation proves so notably beneficial in the class of affections in which it is indicated. The constantly increasing popularity of the preparation in the treatment of respiratory affections is the best adducible evidence of its value in such disorders."

The absurdity of this assertion will be appreciated on comparing the nature, quantities and activities of the several ingredients. Thus, while heroin, a potent habit-forming drug, is present in unusually large proportions, tolu, an innocuous or comparatively harmless product, is said to be represented by ¼ grain, a relatively small quantity, hardly sufficient to impart even a distinctive taste or flavor. Ammonium hypophosphite, in the amount said to be present, may be considered to be practically useless, while the dose of hyoscyamus, an additional narcotic, is fairly large. The white pine bark present is probably as active as would be a corresponding amount of white pine shavings or of turpentine sufficient to give the preparation a slight odor. The vehicle, glycerin, is claimed to be "notably advantageous," but not a word occurs in the discussion by the manufacturer in regard to the presence of alcohol, which is certainly quite as active medicinally as the balsam of tolu and contributes fully as much to the flavor or taste of the preparation as does the white pine bark.

In prominent type on the outer label of the trade package we are told that the preparation is intended for the treatment of "COUGH, ASTHMA, PHTHISIS, PNEUMONIA, BRONCHITIS, LARYNGITIS, WHOOPING-COUGH AND KINDRED AFFECTIONS." In much smaller type: "Glyco-Heroin (Smith) is distinctly a product designed expressly for the use of physicians." The circular included with the trade package, however, bears statements which would tend to encourage self-drugging by the layman, and in view of the manner in which the preparation is exploited are undoubtedly intended to do so. For instance:

> "*Bronchitis.*—In the acute form of bronchitis, Glyco-Heroin (Smith) acts most happily. It tends to diminish the congestion and inflammation of the lining of the air passages, relieves the pain and institutes repair. . . .
>
> "*Phthisis.*—In the treatment of the cough of phthisis, Glyco-Heroin (Smith) is used with the most gratifying results. It checks the night sweats, acts favorably upon the reflexes, increases expectoration and induces refreshing sleep.
>
> "*Asthma.*—The preparation diminishes the intensity of the paroxysms and lengthens the intervals between their recurrence. By the administration of the preparation, asthmatic attacks can frequently be aborted.
>
> "*Pneumonia.*—In the initial stage of pneumonia, the preparation exercises a calming, antipyretic and sedative effect. In the latter stages of the disease, the analgesic and expectorant properties of the product are well displayed.
>
> "*Whooping-Cough.*—Administered in doses of from five to ten drops, this preparation affords surprisingly satisfactory results. The cough rapidly loses its spasmodic character and the frequency of the paroxysms is considerably diminished."

How cruelly misleading the literature put out by the manufacturer of this nostrum is, will be apparent from a comparison of the rather large dose of heroin in a teaspoonful of the nostrum and the directions on the package that:

> "The adult dose of Glyco-Heroin (Smith) is one teaspoonful repeated every two hours or at longer intervals, as the case may require.
>
> "Children of 10 or more years, from a quarter to a half-teaspoonful.
>
> "Children of 3 years or more, 5 to 10 drops."

A WICKED FALSEHOOD

Included in much of the advertising matter that has been put out is the bare-faced untruth that the preparation does not produce narcotism or habituation. Here is a quotation from an undated circular:

> "Glyco-Heroin (Smith) is decidedly preferable to preparations containing codein or morphine, by reason of the fact that it does not produce narcotism, constipation, gastric disturbance nor habituation, even though its administration be protracted."

That this assertion is not in keeping with facts is evidenced by the recent report of a study on the sale and use of heroin made by the U. S. Department of Agriculture. From the information gathered it appears that the sales of heroin and heroin-containing preparations have increased greatly, particularly in those states which have rigid laws preventing the indiscriminate sale of morphin and cocain. Investigation of the subject establishes the fact that many drug victims who formerly used morphin and cocain, and who under the new laws find it difficult to obtain these substances, have begun using heroin, the sale of which is not as yet carefully restricted under state laws. The drug is said to be fully as dangerous as morphin, and by many is held to be much worse, for the reason that it occasionally kills the victim outright, and its habitual use is far harder to overcome than that of other drugs.

Phillips[1] in discussing the prevalence of the heroin habit, reports, among others, the case of a physician aged 61 who began to take heroin because he suffered from a chronic cough and thought there was no danger of habit from the use of this drug because he believed the statements of various manufacturing firms who claimed that there was no danger of habit.

In a pamphlet now being distributed to the medical profession, entitled, "Glyco-Heroin (Smith), an exposition of its components together with references to its value in the treatment of Bronchitis, Cough, Cough of Phthisis, Laryngitis, Pneumonia and allied disorders of the Respiratory Tract," the several alleged uses of the nostrum in the treatment of cough, "Regardless of the nature of its underlying cause, . . . *whether of recent origin or of long duration*," are discussed at length, and eminent practitioners with degrees extending the width of the printed page are quoted in support of the statements made. While it may be permissible for a theoretically trained medical tyro who lays claim to the right of appending the abbreviations M.A., M.D., D.C.L., L.R.C.P. to his name to laud a heterogeneous habit-forming cough-syrup like Glyco-Heroin, Smith, similar testimonials from a man entitled to append Ph.G., M.S., M.D. to his name makes one doubt the value of the training, either scientific, pharmaceutical or medical, that has been given the poor unfortunate who, according to his own statements, indiscriminately doses a female patient of 7 and a male patient of 49 with huge doses of heroin every two, four or six hours.

The danger of contributing to the spread of the heroin habit by the use of preparations of this type is indicated by an editorial in The Journal of the American Medical Association,[2] which points out that although heroin and its hydrochlorid have been in use but a few years they have already established themselves among the habit-forming drugs and have become sufficiently conspicuous in this respect to awaken the thinking public to the deplorable results for which they may become responsible. Phillips,[1] in the article mentioned above, quotes Petty, who reports that in the last 150 cases of drug habit coming under his care he saw eight cases of heroin addiction. Three of these were initial cases; in one the patient had been cured of the opium habit, but following an operation heroin was prescribed, and the habit followed. The remaining four patients purposely substituted heroin for morphin, to which they had been addicted.

---

[1] Phillips, John: Prevalence of the Heroin Habit, The Journal A. M. A., Dec. 14, 1912, p. 2146.

THE GROWTH OF HEROIN ADDICTION

The imminent danger of substituting heroin for either morphin or cocain is shown by the fact, reported by the U. S. Department of Agriculture, that during the early months of 1913 the coroner's office in Philadelphia County, Pa., held inquests on five sudden deaths from heroin poisoning. In each case the victim was a heroin fiend and took an overdose. Drug fiends are apparently able to consume relatively large quantities of morphin or cocain, but any sudden and material increase in the amount of heroin taken is liable to prove fatal. As indicating the wide sale of this substance, it is known that one druggist in Pennsylvania whose store is located in an undesirable section of his city has been buying heroin tablets in 25,000 lots.

GLYCO-HEROIN, SMITH, A "PATENT MEDICINE"

The popularity of Glyco-Heroin, Smith, as a household nostrum is suggested by the fact that one of the larger department-store type of drug-stores in the city of Philadelphia lists this preparation in its "patent-medicine" catalogue at $1.75 per bottle and sells it freely to all who care to buy. This is due to the fact that Pennsylvania, like many other states, does not include heroin in the prohibited list of habit-forming drugs that can be supplied only on physicians' prescriptions.

To what extent Glyco-Heroin, Smith, is responsible for developing the rapidly growing heroin habit is of course problematic. It is reasonable, however, to suppose that a preparation, each teaspoonful of which contains so large a dose of heroin as does this nostrum, when taken as repeatedly and as indiscriminately as is directed by the manufacturer, would offer possibilities for harm sufficient in number to induce the thinking medical practitioner to avoid its use altogether and at least to suggest to even the most commercial dabbler in the healing art the desirability of carefully considering its potency for harm before endorsing its use in the treatment of "cough and kindred affections."

AN EXPLANATION

It is never the intention of The Journal to do an injustice. Authenticated statements made to us relating to our article of April 11 regarding Wine of Cardui, manufactured by the Chattanooga Medicine Company, prompts the publication of the following:

The Chattanooga Medicine Company claims that only the alcohol needed as a solvent and preservative is used in the preparation of Wine of Cardui and that alcohol is only used for those purposes. They assert that they have employed leading chemists who have sought widely for another preservative, but without success, and that they once tried 5 per cent. and again 3 per cent. less alcohol but found that hundreds of cases of the preparation spoiled as a result of insufficient preservative. They state that the taste of the infusion is such as to prevent its use as a beverage and that it is not so sold or used, in fact that in too large doses the preparation has been found to act as an emetic. Based on the foregoing statement it is apparent that the terms "booze" and "tipple," as these words are commonly understood, cannot be applied to the preparation.

The concern says that when the present managers took control in 1906, they eliminated from the wrappers claims that, although for about thirty years presented in that same form, they felt might fairly be regarded as extreme; that their present desire and intention is to avoid on the wrappers or elsewhere claims that might reasonably or generally be objected to as extravagant.

In The Journal's article, John A. Patten, the principal owner of the Wine of Cardui business, was referred to, and his high standing in the organization of the Methodist Episcopal Church emphasized. To offset The Journal's criticisms, many letters are submitted to show that Mr. Patten is a man of high personal standing, and "that his relation to his church is based on his ability and service rather than on any financial gifts he may or may not have made."

Association News

PROGRAM OF PHILADELPHIA CLINICS

The following clinics have been arranged by the Committee on Clinic Days and will be held in Philadelphia on Monday, June 22, and on Friday and Saturday, June 26 and 27—the day preceding and the days following the Scientific Assembly of the Association. Fellows who attend the coming annual session can readily arrange to spend two days in Philadelphia by planning to reach that city on the morning of June 22. An hour's run in the evening will enable them to reach Atlantic City. In the same manner, they can arrange to spend the end of the week at these clinics.

Frederick Douglas Hospital, 1530 Lombard Street:

Monday, June 22.
11 a. m. Gynecologic Clinic. J. Q. McDougald.
5 p. m. Lecture Mental and Nervous Diseases. Alfred Gordon and R. W. Bailey.
Saturday, June 27.
11 a. m. Tuberculosis. C. A. Lewis.
Tinea Tonsurans. John P. Turner.

Gynecean Hospital, 247 North Eighteenth Street:

Monday, June 22.
9 a. m Gastroptosis. Henry D. Beyea.
10 a. m. Hysterectomy. Theodore A. Erck.
12 m. Hysterectomy. Brook M. Anspach.
Saturday, June 27.
9 a. m. Cystocele and Rectocele. George W. Outerbridge.
10 a. m. Prolapse of the Uterus. Henry B. Ingle.
11 a. m. Retroversion. J. Watson Martindale.

Episcopal Hospital, Front Street and Lehigh Avenue:

Monday, June 22
11 a. m. Abdominal Operation. L. H. Mutschler.
12 m. General Surgery. Thomas R. Neilson.
1 p. m. Orthopedic Clinic. Astley P. C. Ashhurst.
Saturday, June 27.
9 a. m. Surgical Clinic. Astley P. C. Ashhurst.
11 a. m General Surgery. Emory G. Alexander.
2 to 4 p. m. Inspection of Hospital. Astley P. C. Ashhurst.

Philadelphia General Hospital, Thirty-Fourth and Pine Streets:

Monday, June 22.
10 a. m. Tuberculosis. A. P. Francine.
11 a. m. The Anemias. J. H. Musser, Jr.
12 m. Neurologic Clinic. Charles S. Potts.
1 p. m. Cerebral Palsies. D. J. McCarthy.
2 p. m. Tuberculosis in the Home. Ward Brenton.
3 p. m. Operations on the Eye. J. W. Croskey.
3 p. m. Vulvovaginitis in Children. H. C. Carpenter.
Saturday, June 27.
11 a. m. Gynecologic Clinic. Ella B. Everitt.

Jefferson Medical College Hospital, Tenth and Sansom Streets:

Monday, June 22.
11 a. m. Obstetric Clinic. E. P. Davis.
11 a. m. Neurologic Clinic. F. X. Dercum.
12 m. Dermatologic Clinic. H. W. Stelwagon.
12 m. Cardiovascular Disease. H. A. Hare.
12 m. Nose and Throat Cases. D. Braden Kyle.
1 p. m. Medical Clinic. S. Solis-Cohen.
2 p. m. Ophthalmologic Clinic. W. M. Sweet.
3 p. m. Surgical Clinic. F. T. Stewart.

Friday, June 26, a Special Clinic for the Class of 1874 of the Jefferson Medical College, in the Clinical Amphitheater from 10 a. m. to 2 p. m. E. E. Montgomery. All physicians are welcome.

Saturday, June 27.
9 a. m. Medical Clinic. Thomas McCrae.
9 a. m. Gynecologic Clinic. E. E. Montgomery and J. M. Fisher.
10 a. m. Orthopedic Surgery. H. A. Wilson.
11 a. m. Surgical Clinic. John H. Gibbon.
11:30 a. m. to 1 p. m. Renal Surgery. H. R. Loux.
1 p. m. Pediatric Clinic. E. E. Graham.
3 p. m Surgical Clinic. F. T. Stewart.

---

[2] Facts About Heroin, Current Comment, The Journal A. M. A., Dec. 21, 1912, p. 2262.

HOWARD HOSPITAL, 801 South Broad Street:

Monday, June 22.
12:30 p. m. Surgical Clinic. Barton Cooke Hirst.

ST. JOSEPH'S HOSPITAL, Sixteenth Street and Girard Avenue:

Monday, June 22. In the East operating-room:
8:30-10 a. m. Uterine Prolapse. P. B. Bland.
10 a. m. Retrodisplacements of the Uterus. F. Hurst Maier.
11 a. m. Abdominal Surgery. Melvin M. Franklin.

MEDICAL MISSIONS AT THE ATLANTIC CITY SESSION

The Catholic members of the American Medical Association who are interested in medical missions are invited to apply for further information to, P. J. Flagg, M.D., the Marlborough Blenheim, Atlantic City, or Maryknoll, Ossining, N. Y.

Correspondence

A Caffein Addict with Asthenopic Symptoms

To the Editor:—Miss Y. A., aged 18, office clerk, of slight stature, frail physique and attentive and refined disposition, for four years had had the ordinary symptoms of asthenopia, which had been worse for several months. Refraction under complete cycloplegia showed hyperopic astigmia, axes oblique. A full correction was provided, which, to my surprise, gave but little relief. The correction was verified by repeated examinations and the most careful attention paid to the adjustment of the frames, but the symptoms continued. The patient became eccentric and stubborn, at times exhilarated, then depressed, and would exhibit lapses of memory and deportment with an indifference to the usual conventionalities and proprieties. The headaches were intermittent and not caused by near work, but were always increased by it in an attempt at reading, etc., during an attack. Insomnia was present at night, yet she would fall asleep at her work during the day.

Affairs were becoming serious and I was at my wits' end when one day the patient asked if there could be any danger in an overindulgence in Coca-Cola, stating that she drank from three to six glasses a day. In addition, she had two or three cups of strong coffee at mealtime, sometimes taking but little other nourishment. Curtailing the amount of daily ingestion of caffein caused a prompt improvement in all symptoms, but unfortunately there is a possibility that the patient has acquired some rather detrimental incidental habits which will require a longer time for elimination.

I feel that such a case is of interest from an ophthalmologic point of view and also that it indicates that the profession should be more alive to the pernicious influence in habit formation of some of the popular beverages served to young persons at public "slop" fountains.

Otis Orendorff, M.D., Canon City, Colo.

A Simple Method of Vaccination

To the Editor:—After reading Dr. Force's article on "An Investigation of the Causes of Failure in Cow-Pox Vaccination" (The Journal, May 9, 1914, p. 1466), in which he mentions the successful use of the von Pirquet borer in vaccinating against small-pox, I would call attention to my article on "A Simple Method of Applying the von Pirquet Test" (The Journal, July 5, 1913, p. 27), which has been used successfully in hundreds of cases. I use the flat end (2 mm. wide) of sterile wooden toothpicks instead of the metal von Pirquet borer. It seems to me that this would be ideal, because the simplest technic of any, for cow-pox vaccination. After the arm is cleansed, the flat end of the sterile wooden toothpick would be dipped in the vaccine and gently pressed on the desired spot on the skin. While the toothpick is held in the middle by the thumb and index-finger, a few turns made by rolling the toothpick to and fro on its own axis between the fingers would result in a neat round abrasion of the epithelium without the appearance of blood. The use of a separate toothpick for each vaccination would insure all the advantages that go with absolute cleanliness and utmost simplicity. Louis Shalet, M.D., New York.

Phonograph in Operating-Room

To the Editor:—For some time I have been employing a phonograph in my operating-room as a means of calming and distracting my patients from the horror of the situation when going under the anesthetic and during operations performed partially or entirely with local anesthesia. The phonograph talks, sings or plays on, no matter how anxious, busy or abstracted the surgeon, anesthetist and assistants may be, and fills the ears of the perturbed patient with agreeable sounds and his mind with other thoughts than that of his present danger. Too often when told to keep up an agreeable conversation with our patients operated on under "local," the assistants merely ask again and again if the sufferer is being hurt or if he feels ary pain, thus only adding to the self-consciousness of the patient, and, after weather commonplaces are exhausted, it seems impossible to find a topic for conversation of any sort, and dead silence ensues. It is not uncommon for nervous patients to beg to have the phonograph continue, should it run down, and many of them converse animatedly with the anesthetist on the subject of the pieces being played throughout the entire operation.

I owe to Dr. Burdick, our anesthetist, thanks for his selection of records admirably adapted to the tastes and temperament of the subjects.

Evan O'Neill Kane, M.D., Kane, Pa.
Surgeon, Kane Summit Hospital.

Cholesterinized Antigens

To the Editor:—In The Journal, May 9, 1914, p. 1458, there is an article by Dr. Loyd Thompson on the use of cholesterinized antigens in the Wassermann reaction, in which he strongly disagrees with the findings reported by us in a previous article (The Journal, Jan. 31, 1914, p. 363), asserting that his series of 356 tests is a larger series than ours from which to draw conclusions. As a matter of fact, the number of cases in which Thompson employed the cholesterinized antigen controlled by the syphilitic liver antigen was only 50, as compared with 133 cases in our series. The results given by Thompson, based on examination of 306 cases in which the cholesterinized extract alone was used, obviously furnish no basis of comparison between the merits of the two antigens, and we feel that we should have obtained practically the same results with syphilitic liver antigen. Arguing from Thompson's point of view, we might cite the results of 2,500 cases in favor of syphilitic liver antigen, uncontrolled by cholesterinized extract.

In regard to the suggestion that the discrepancy in the results of Thompson's work and ours may be accounted for in the titration of reagents, we may state that the technic for titration of complement, etc., recommended by Thompson is almost identical with one that has been used by us for over a year, which was presented before the Pathological Society of Philadelphia in January, 1914, and which is in press for publication in an early issue of the *American Journal of the Medical Sciences.*

B. A. Thomas, M.D., and R. H. Ivy, M.D., Philadelphia.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

OBSTETRIC ANESTHESIA BY SCOPOLAMIN AND MORPHIN

To the Editor:—Can you refer me to any recent article on scopolamin-morphin anesthesia as practiced by Bernhardt Krönig and Karl Gauss at the Freiburg clinic, Baden?

J. P. McMahon, M.D., Milwaukee, Wis.

To the Editor:—Is the twilight sleep method of anesthesia in obstetrics by scopolamin and morphin known in the United States as to formula, and does any pharmaceutical house put out the preparation used in the Freiburg clinic in Germany referred to in the June number of *McClure's Magazine?*

What is considered the most up-to-date obstetric anesthesia aside from the use of chloroform and ether?

E. E. Sweeney, M.D., Grafton, Neb.

To the Editor:—What is the present status of morphin-scopolamin anesthesia among obstetric authorities?

W. O. Wilkes, M.D., Waco, Tex.

Answer.—Aside from the foregoing, we have received many letters regarding the article referred to. It is extremely unfortunate that a popular magazine such as *McClure's*, the efforts of which in the past in behalf of true medical science have been so influential for good, should have published such a sensational and misleading article without due consideration of its effect on the public. It would seem that the editor of a magazine publishing an article on a scientific subject, especially one discussing such an important subject as this, would consult some competent medical authority as to the underlying facts. The public on reading this article would naturally infer that this method of analgesia was something new. As a matter of fact, our readers of course know that the suggestion for the use of a combination of scopolamin (hyoscin) and morphin was made over 12 years ago, and was put to a pretty thorough test, especially in Germany. While it is not altogether obsolete, it has been practically discarded.

Another natural inference would be that an obstetrician would be negligent of his patients' rights if he withheld the scopolamin-morphin method in his labor cases. The facts are that this method has been thoroughly investigated, tried and found wanting, because of the danger connected with it. Even the most enthusiastic among its German advocates have emphasized its danger, and have stated that it should not be used except in hospitals, where constant, careful watching is possible.

The *McClure's* article seems to have been written, however, especially to emphasize the remarkable results obtained in Freiburg by Krönig and Gauss. As a matter of fact, the Freiburg method differs but slightly from that originally suggested. By the Freiburg method one dose of morphin is given, whereas the scopolamin is repeated as indicated—the indication being, not pain, but memory.

The history of the method is of interest in showing its development. Steinbüchel of Graz began with small doses of morphin and scopolamin and had no unfavorable results, that is, no dangerous results. Those who followed him used repeated doses of morphin as well as scopolamin—sometimes excessively large doses, with the result that there were serious consequences, particularly the death of the infant. In 1907 a special technic was elaborated by Gauss in the clinic of Krönig at Freiburg in Baden. The technic of Gauss is substantially as follows: The object aimed at is to make the parturient woman forget her pains, although she may be conscious of them at the time; the condition known as "twilight slumber" (*Dämmerschlaf*) is produced. In order to test the mental condition of the patient, she is shown some object and after an interval of about half an hour, this object is again called to her attention. If she remembers having seen it before, she is not sufficiently amnesic, and an additional dose of scopolamin is given. It should be remembered that the method of Gauss is not correctly represented by the frequent recommendations to use scopolamin-morphin for the relief of pain in labor. Let it be emphasized that but a single dose of morphin is used. In this way the frightful mortality that occurs in infants from morphin injections is largely eliminated.

Scopolamin also has its own dangers. Small doses sometimes produce very serious results. There may be great disturbances of the nervous system, or of the heart and lungs. It is impossible to predict when these results may follow its administration and they cannot be guarded against. Proprietary preparations containing fixed quantities of the two alkaloids cannot be successfully used to secure the results desired.

The impression gained from a review of the literature is that the present method of obstetric anesthesia by scopolamin and morphin is not safe for the child and not always safe or successful for the mother. The time may come when the hope expressed in 1911 by Lequeux may be fulfilled, that further clinical investigations cautiously conducted will secure a harmless agent with which to lessen or abolish altogether the pains of labor; but that time has not yet arrived.

STEROLS AND THE BIOCHEMISTRY OF BACTERIA

To the Editor:—In your Current Comment last week on "The Biochemistry of Bacteria" (The Journal, May 30, 1914, p. 1730, you speak of "sterols." Can you give a clearer definition of this term? You speak of cholesterol as being a familiar example of sterols. What relation does cholesterol bear to sterols? Are they chemical derivatives or are they related by their physical properties? I am trying to keep up with the progress medicine is making, but find it difficult to do so when words like this are used that do not appear in the dictionaries.

J. H. S.

Answer.—When animal tissues are extracted with ether they yield to this solvent a mixture of true fats along with that heterogeneous group of substances at present familiarly known as "lipoids." If the ether extract is saponified with an alkali there remains, admixed with the soaps and other products formed in the reaction, an unchanged substance at one time called a "non-saponifiable" fat, and better known as cholesterin. This is a monohydric alcohol of the formula $C_{27}H_{45}OH$; its exact constitution is still unknown, although a great deal of research has been devoted to it. In conformity with modern nomenclature in organic chemistry, whereby the alcohols receive the ending "ol," the compound just referred to is now as a rule spoken of as cholester*ol*, precisely as one alludes to the alcohol phen*ol* or cres*ol*.

While cholesterol has been isolated uniformly from the tissues of mammals and birds, whenever the lipoid bodies contained in them have been investigated, with one or two exceptions no other substance similar to it had, until quite recently, been discovered in animal protoplasm. From the vegetable kingdom, on the other hand, a large number of bodies, isomeric with and no doubt closely related to, cholesterol, have been obtained—the phytosterols. Although recent observations show that the number of these is perhaps not so great as was at one time supposed, owing to the fact that many of the products described under different names are mixtures of phytosterols, nevertheless not only do many substances of this general type exist, but frequently, different forms occur in the same plant, each associated with one or other of the plant structures.

More recently the study of the distribution of these nonsaponifiable ether-soluble products has been extended to include all orders of animals from the chordates to the coelenterates. The results indicate that the protoplasm of all animals examined, and, therefore, probably of all animals, contains at least one member of the cholesterol family. The individual products isolated, differing in certain undeniable physical and chemical properties such as crystalline form, melting points, etc., have been variously named, usually to indicate their origin in nature. Thus we have sitosterol, bombicesterol, clionasterol and coprosterol, among others. To give some inclusive or generic name to cover all of these varied evidently related substances derived from animals and plants, the word "sterin," or better, "sterol," has been adopted of late. The sterols have, in turn, been classified by Dorée (*Biochem. Jour.*, 1913, vii, 618) into zoosterols (from animals), phytosterols (from plants) and matasterols the latter common to animals and plants. For a recent review of the subject the reader is referred to Windaus: Die Sterine, in Abderhalden's Biochemisches Handlexikon, iii, 268, and to the paper of Dorée mentioned above.

STATES RECIPROCATING WITH NEW YORK

To the Editor:—Please inform me with what states New York has reciprocal relations.

C. J. B.

Answer.—New York has established reciprocal relations with Delaware, Indiana, Michigan, New Jersey, Ohio, Utah and Wisconsin.

BAELZ' DISEASE

To the Editor:—A patient came to me with what I diagnosed as eczema of the lip. There is no history of syphilis. He had been told by a physician that it was Baal's disease and that it was very rare. As I can find nothing in regard to this rare disease in my text-books, will you please inform me?

M. F.

Answer.—"Baal" is probably a misspelling of "Baelz." Baelz' disease is a form of cheilitis glandularis or myxadenitis labialis. It is described by Unna in an article "Ueber Erkrankungen der Schleimdrüsen des Mundes" (*Monatsh. prakt. Dermatol.*, 1890, xi, 317).

It is an inflammation of the mucous glands of the lip and the periglandular tissue, affecting chiefly the lower lip. In Unna's cases the mucous glandular swelling went on to pronounced suppuration, crusting and ulceration and then cicatrization. Unna found that local treatment with tincture of iodin acted as a specific, improvement ensuing immediately.

CRITICISM OF PRESCRIPTION

To the Editor:—Please explain to me what should be the result of the following combinations:

Phenacetin	gr. ix
Codein sulph.	gr. ⅓
Aspirin	gr. vi
Sugar of milk	gr. vi

Take with glass of water three times a day.

P. J. B. LeBlanc, M.D., Fairbanks, Alaska.

Answer.—There is no chemical or physiologic incompatibility in this prescription. The remedies are synergistic and the doses, though rather large, are not above what might be given in some cases.

Medical Economics

This Department Embodies the Subjects of Post-graduate Work, Contract Practice, Legislation, Medical Defense, and Other Medicolegal and Economic Questions of Interest to Physicians

A LAYMAN'S VIEW OF OSTEOPATHY

A bill giving osteopaths all the rights of regularly qualified physicians recently passed the New York legislature and was sent to Governor Glynn for signature. He held a hearing on the bill, April 13, at which Mr. Abraham Flexner, one of the secretaries of the General Education Board, presented a statement of the present condition of osteopathic schools, as found by a personal inspection of them. Mr. Flexner's statement is of value as showing the fallacy of the educational and scientific claims of osteopathy. Mr. Flexner said:

"Your Excellency, as you doubtless know, I am not a physician. I have no practice to protect, and no particular school of medicine to defend or apologize for. I am in the exceptionally advantageous position of having freely criticized medical schools of all denominations. This criticism was based on a study of medical education in the course of which I visited every medical school in the United States and Canada, and saw every nook and corner of them. Subsequently I visited not all, but most of the medical schools in Europe.

"The general difference between the osteopathic schools, as I found them in 1909 and 1910, and the other medical schools is this: Among regular and homeopathic medical schools there were some good and some bad. The osteopathic schools were all bad.

"The gentlemen who will be privileged to practice medicine in the state of New York, if your Excellency signs this bill, were graduates of the eight osteopathic schools which I visited in 1909 and 1910, having all graduated previously to my visit and under conditions that were probably worse than those which I saw during that time.

"I wish now to describe to you, school by school, exactly what I observed at that time. We will assume that the schools as they passed through them were as good as they were when I visited them.

"In the first place, I have here the catalogues of all those schools of the years 1909 and 1910, just about the time when I visited them, and a little subsequently to the time during which these gentlemen passed through them.

"The most striking general characteristic of the schools at that time was their outspoken and purely mercenary character. Without a single exception they were conducted, and very efficiently and energetically conducted, as business enterprises for the making of money.

"You will see in a moment, when I come to speak of the entrance requirements, that the entrance requirements were so low that practically anybody might enter them on application. In order to get large numbers of students of this low academic grade, the schools indulged not only in all kinds of undignified advertising, but circulated the catalogues, which I have here, and which were intended to be simply an appeal to crude commercial interest. I am going to quote you something from each of these catalogues.

"The following is from the catalogue of one of the Los Angeles schools:

> "'People are ready to pay for relief from distress and sickness. Many of our graduates are earning as much in a single month as they were formerly able to earn by a full year's work. Ninety-seven per cent. of all our graduates of the past are to-day earning their living in the practice of osteopathy. We mention these facts because the uninitiated young man or woman is entitled to know.'

"Again, later:

> "'Prospective students may be sure of employment during their leisure hours.' (You can imagine how much of leisure a two-year course should allow!) 'Any young man or woman who is able to arrange for the tuition can master the course. Osteopathic treatments are given to *students without expense*. The saving in bills for treatment has in some cases more than covered the cost of tuition.'

"There is a second Los Angeles school called the Pacific College, from the catalogue of which the following is taken:

> "'It is safe to say that in no case has a competent osteopath made a failure in his attempt to build up a paying practice. His remuneration, counted in dollars, would be greatly in excess of what he could expect to receive in most other lines of professional work.'

"From the Des Moines school catalogue is taken the following:

> "'The profession will yield better returns than any other profession.'

"This, from the Philadelphia school catalogue:

> "'A lucrative practice is assured to every conscientious and capable practitioner.'

"From the Massachusetts school is the following:

> "'Osteopathic students can step at once into a paying practice. Seventy per cent. of the graduates of osteopathic colleges succeed financially, while only 7 per cent. of those from other medical colleges are thus successful. Osteopathy is one of the best-paid professions in the world to-day. Any one who is dissatisfied with his or her calling in life might well consider osteopathy. The rewards are many and adequate Financially, a three years' course in osteopathy is an exceedingly good investment. The Massachusetts College of Osteopathy graduate who does not make as much as the total cost of his osteopathic education in his first year of practice is in exception. What other investment can possibly be made that will yield 100 per cent. or more first year out, and at least as much as that each year thereafter?'

"From the Central College in Kansas City:

> "'The average osteopath has a better practice than ninety out of every hundred practitioners. The young osteopath builds up a practice *in less time than the regular practitioner*.'

"This, then, is the nature of the appeal, your Excellency, addressed to the kind of candidate that I am now going to describe to you.

"Medical schools offer, including osteopathic schools, instruction in anatomy, chemistry, physiology, pathology, surgery, obstetrics, and so on. In order to be sure that students will be able to grasp such difficult and exacting subjects, it is necessary, and has been found necessary in all states, to insist on a minimum academic preparation.

"The preparation in the state of New York now is, at the very least, a four-year high-school course, which shall include a year each in chemistry, physics and biology.

"Now I am going to read you the entrance requirements in the various osteopathic schools as I found them in 1909 and 1910, about the time when the gentlemen who will be beneficiaries of this law if signed were graduated. The following is from the catalogue of the Los Angeles school:

> "'In order to be admitted to this school, a student must show evidence of proper training' (I call your attention to the fact that it does not provide submission to an examination) 'in English, mathematics, history, geography'—that is to say, less than a common-school education.
>
> "'Moreover' (and this is a verbatim quotation), 'candidates found deficient in one or more of these four subjects may be admitted on condition.'

"That is, there was no academic requirement whatsoever for admission to the Los Angeles school at the time of my visit. Anybody who could pay the fees went in.

"The following is from the Des Moines school:

> "'Evidence of proper training in English grammar, arithmetic, U. S. history, geography and elementary physics.'

"Evidently, very elementary physics, since it was only such physics as might be taught to a student whose mathematical knowledge consisted in knowing simple arithmetic.

"The following is from the Philadelphia school:

> "'Candidates for admission must have good moral character, good health, and student qualities.'

"Any kind of a credential was at that time accepted there, and no examination was required. The specifications in the catalogue were as vague as those I have quoted.

"The following is from the Massachusetts school:

> "'Evidence of proficiency, but no examination, in spelling, punctuation, arithmetic, history, geography and the elements of physical science.'

"The following is from the Kirksville school, which is the parent school. By the way, Kirksville

> "' . . . is commended to the prospective student on the ground that Kirksville is the home of osteopathy, with a good business college, three newspapers, two first-class hotels, scores of boarding-houses, five livery and feed stables, a steam laundry, three planing-mills, a shoe factory 700 by 300 feet in dimensions, many residences heated by hot water, and last and by no means least local option adopted by a two-thirds majority. . . . In order to enter this school the student must know English grammar and composition, rhetoric, arithmetic (including compound numbers and percentage) history and geography.'

"But if he fail to satisfy these exacting requirements, the student may be admitted without them.

"The following is from the Central College at Kansas City:

> "'Students must furnish creditable evidence of a good moral character and of practical training in the common branches.'

"In other words, there was not a single osteopathic school in the country that had any definite entrance requirements whatsoever. How can this state, having set up a standard and forced compliance therewith, open the doors to low-grade osteopathic graduates from other states less intelligently governed?

"Again, in respect to their facilities for teaching: If you will consult the catalogues, you will see that all these schools make a pretense of teaching all the laboratory branches required in the most exacting schools. And of course it is obviously necessary, in order to make a diagnosis, that the physician, to be a good osteopath, should understand chemistry, physiology, pathology, and anatomy especially, as it is the backbone of their science. At the time I visited these schools, *not a single osteopathic school in the country* possessed a decent laboratory in any subject, not even in anatomy.

"I will read to you, taken from my note-book which I have here, and which I shall be glad to leave with you, my description of the laboratory equipment of these schools, notes made as I passed from room to room under the chaperonage and guidance of one of the instructors, or the dean.

"The first one is the Des Moines school, and is as follows:

> "'The laboratory outfit is almost altogether made up of signs. There was a room with "anatomy" painted on the door which proved to be an empty amphitheater. There was a room with the word "physiology" painted on the glass door, which turned out to be a practically empty class-room with a few chairs and a few things in a book-case and no laboratory equipment whatsoever. A room marked "chemistry" was a disorderly and disarranged room with less equipment than would be needed in an elementary high school to teach chemistry. There were two or three incubators in the same room. There was another room marked "histology," which was locked, and nobody on the premises had a key to it. It was claimed that there were forty microscopes on the inside. There was also an "anatomy" room, which was a dirty and disorderly dissecting-room, in which there was an uncovered vat containing a single soaking body, party dissected and decaying. One or two tables apparently were in use in that room. On the floor back of the office there was also a room marked "Physics," the sole outfit of which was a friction electric machine. This room was not a class-room. This, then, was the laboratory equipment used in teaching 115 students.'

"The Littlejohn College of Osteopathy, which I think now is called the Chicago College, was visited. There were a number of absolutely bare class-rooms. No laboratories were in use at the time of my visit, because the college was undergoing expansion, and all the laboratories had been dismantled except the chemical laboratory, which had a simple equipment. When I suggested that perhaps all laboratory instruction had been temporarily suspended owing to the necessities of reconstruction, I was assured that that was not the case.

"In the Philadelphia school I found that each class has a separate room, all subjects taken by the class being apparently taught in that room. Instead of having rooms for anatomy, physiology, and so on, there was a room for seniors, sophomores, juniors, etc. This arrangement stamped it at once as simply a didactic school. The freshman room was bare, except for a few crude drawings, a case of bones, a model and a skeleton. There was another room in this school called the junior room, which was practically the same, with the exception that there were no bones in it.

"Then there was another room not designated as belonging to any special class, in which there was a stereopticon. There was also a histological laboratory with a small centrifuge and an invisible microscope. A small chemical laboratory was found in a dark and dingy cellar. There was absolutely no provision whatsoever for pathology, physiology or bacteriology, no museum and no books. There was a dissecting room, however, in a dark old stable in a horrible condition.

"The Kansas City school was called the Central College. At this school I found a small and very meager laboratory in chemistry. There was no other laboratory equipment worthy the name, not even in anatomy. The teacher of anatomy told me that students ought to know anatomy before dissecting. One body had been obtained in September and had been used up. Another was expected in February. When I asked the teacher in anatomy how he taught anatomy without a body, he said it was a simple matter; that if they taught a student anatomy before he began to dissect, his progress was quicker, and that therefore they had no use for a body at that time.

"I now come to the Kirksville school, which is the most pretentious and largest of them all, having almost six hundred pupils. There I found one room which was used for short six-week courses in bacteriology and physiology, in *which thirty-two persons could be accommodated*. There was one preparation room which was used for all laboratory subjects. The school was owned by two doctors who were more interested in fine cattle than in good school equipment. It had proved a very profitable investment, and the profits are invested, so I was informed by the people there, in a splendid stock farm. In the school there were four lecture-halls absolutely bare except for chairs; one small but fairly well-equipped chemical laboratory; a simple dissecting-room; a laboratory for histology and pathology, but no museum, and no gross pathological material.

"The Cambridge, or Massachusetts, School of Osteopathy had one small laboratory for pathology, bacteriology and histology, and one for chemistry. It had no laboratory for physiology, no museum, no books, and anatomy had been *postponed one month on account of lack of available* material.

"I think it is perfectly safe to say that on the laboratory side, the very worst regular homeopathic medical schools in the United States were at least as good as the best osteopathic schools at that time, and that regular and homeopathic schools of that type would have absolutely no standing before the Board of Regents of New York.

"As to clinical conditions: The backbone of the medical school is its clinical opportunities. Let me describe to you what existed at that time in this direction:

"*Kansas City.*—The school had absolutely no hospital facilities of its own, and no clinical connection where students could be taught. By paying a five-dollar fee its students were able to attend city hospital clinics given by the regular medical college. There was a small dispensary operated at the college, at which patients paid for the treatment they received. Practically, therefore, there were no clinical facilities whatsoever.

"*Kirksville.*—The parent school, with practically six hundred students at the time I visited it, had a hospital with *fifty-four beds, most of them containing the surgical* cases operated on in the good old way, with the knife, despite the fact that osteopathy is 'drugless and knifeless healing.' There were very few obstetrical cases, but a large dispensary where most of the treatments were paid for by the patients.

"*Philadelphia College.*—Here the clinical facilities consisted of a small hospital several blocks away from the school building, containing three beds. The catalogue states that the students have the privilege of witnessing operations at the University and Jefferson hospitals, performed by regular surgeons, the former belonging to the University of Pennsylvania and the latter belonging to the Jefferson Medical College. I made inquiries at both these institutions, and was told that the statement printed in the catalogue is untrue, and that any student of the Philadelphia College of Osteopathy who penetrated into these clinics was an intruder and a trespasser without rights or privileges of any kind.

"*Massachusetts.*—This school had clinical facilities at the Chelsea Hospital, a pay institution of less than fifteen beds and over an hour's journey from the college building.

"*Des Moines.*—This institution at the time of my visit to it had no hospital of any kind whatsoever, but I was told there was a pay hospital to be opened there shortly.

"*The Los Angeles College.*—This school also had a small pay dispensary, and a pay hospital under construction, which I presume has since been opened.

"The second Los Angeles college, the so-called Pacific College, had a hospital which it claimed as its own, and which is made much of in the catalogue. But I found, on closer inquiry, that students had no access to it.

"So that, on the clinical side, as on the laboratory side, these gentlemen have had practically a didactic training on an educational basis amounting to less than a common-school education.

"Now, if this bill is signed, these gentlemen will have the privilege of practicing in the state of New York precisely *as though they had been graduated from institutions* which maintain under the strict scrutiny of the State Department of Education a high entrance basis, and which are required by the State Department of Education to maintain expensive laboratories and elaborate clinics.

"Aside from the specific question here involved and aside from the discussion we heard up-stairs on Christian Science, there is a much wider question involved, namely, What is the duty of a modern state in respect to medical education?

"We have, with great difficulty, in the face of great opposition, and with an enormous expenditure of money and effort, built up in the state of New York a structure which makes

New York perhaps at this moment the best protected state in the Union in respect to sanitation and public health.

"The state of Illinois, the virtues of which were commended to us by an eloquent orator a few moments ago, is one of the least enviable in the Union, in this regard. There is more quackery rampant in the city of Chicago than in any other city in the Union.

"This is not a question of personal liberty. A modern state does not regulate its technical affairs by means of universal suffrage. In regard to the conservation of life and health, it is the function of the modern state to inquire into and to ascertain what is the best thing that can possibly be done. Having ascertained that, the state, for the benefit of those directly and indirectly affected, insists that we must all drink pure water, must notify the authorities of infectious diseases, and have well-ventilated and wholesome factories; these things are best for those immediately concerned and best in the long run for the entire community.

"That is the real question at issue in all this legislation. It is not a question of individual liberty. It is a question of the state using its statutory powers for the benefit of those who are in no position to protect themselves. The state must forbid the practice right to healers and untrained osteopaths for fear that the ignorant and misguided may injure themselves and others."

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Alabama: Montgomery, July 14. Chairman, Dr. W. H. Sanders, Montgomery.

Arizona: Phoenix, July 7-8. Sec., Dr. John Wix Thomas, Phoenix.

California: Los Angeles, June 16. Sec., Dr. C. B. Pinkham, 135 Stockton St., San Francisco.

Colorado: Denver, July 7. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

Connecticut: New Haven, July 14-15. Sec., Dr. Chas. A. Tuttle, New Haven. Homeopathic: New Haven, July 14. Sec., Dr. Edwin C. M. Hall, New Haven. Eclectic: New Haven, July 14. Sec., Dr. T. S. Hodge, 19 Main St., Torrington.

Delaware: Dover and Wilmington, June 16-18. Sec., Dr. H. W. Briggs, 1026 Jackson St., Wilmington.

Florida: Palatka, June 17-18. Sec., Dr. E. W. Warren, Palatka.

Indiana: Indianapolis, July 14-16. Sec., Dr. W. T. Gott, State House, Indianapolis.

Iowa: Iowa City, June 11-13. Sec., Dr. Guilford H. Sumner, State House, Des Moines.

Kansas: Kansas City, June 9-12. Sec., Dr. H. A. Dykes, Lebanon.

Kentucky: Louisville, June 15-17. Sec., Dr. A. T. McCormack, Bowling Green.

Maine: Augusta, July 7-8. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.

Mary[illegible] lar Board: Sec., Dr. J. McP. Scott, [illegible] nore, June 15. Sec., Dr. O. N. Duvall, [illegible]

Michigan: Ann Arbor, June 9. Sec., Dr. B. D. Harison, 504 Washington Arcade, Detroit.

Mississippi: Jackson, June 16-17. Sec., Dr. E. H. Galloway, Jackson.

Missouri: St. Louis, June 15-17. Sec., Dr. J. A. B. Adcock, Jefferson City.

Montana. Helena, June 30-July 2. Sec., Dr. Wm. C. Riddell, Helena.

New Hampshire: Concord, July 1-2. Regent, Mr. H. C. Morrison, Concord.

New Jersey: Trenton, June 15-16. Sec., Dr. H. G. Norton, 429 E. State St., Trenton.

New Mexico: Santa Fe, July 13. Sec., Dr. W. E. Kaser, East Las Vegas.

New York: June 23-26. Chief of Examinations Division, Mr. Harlan H. Horner, Department of Education, Albany.

North Carolina: Raleigh, June 9. Sec., Dr. Benj. K. Hays, Oxford.

North Dakota: Grand Forks, July 7. Sec., Dr. G. M. Williamson, Grand Forks.

Oklahoma: Oklahoma City, July 14. Sec., Dr. John W. Duke, Guthrie.

Oregon: Portland, July 7-9. Sec., Dr. L. H. Hamilton, Medical Bldg., Portland.

Rhode Island: Providence, July 2-3. Sec., Dr. Gardner T. Swarts, State House, Providence.

South Carolina: Columbia, June 9. Sec., Dr. A. Earle Boozer, 1802 Hampton Ave., Columbia.

South Dakota: Deadwood, July 14. Sec., Dr. Park B. Jenkins, Waubay.

Texas: Austin, June 23-25. Sec., Dr. W. L. Crosthwait, Waco.

Utah: Salt Lake City, July 6-7. Sec., G. F. Harding, 405 Templeton Bldg., Salt Lake City.

Virginia: Richmond, June 23-26. Sec., Dr. Herbert Old, Norfolk.

Vermont: Burlington, July 14-17. Sec., Dr. W. Scott Nay, Underhill.

Washington: Seattle, July 7. Sec., Dr. C. N. Suttner, Baker Bldg., Walla Walla.

West Virginia: Elkins, July 1. Sec., Dr. S. L. Jepson, Wheeling.

Wisconsin: Milwaukee, June 29. Sec., Dr. John M. Beffel, 3200 Clybourn St., Milwaukee.

Wyoming: Laramie, July 9-11. Sec., Dr. H. E. McCollum, Laramie.

The Eighth Report of the Carnegie Foundation for the Advancement of Teaching

The eighth annual report of the president of the Carnegie Foundation for the Advancement of Teaching, recently made public, shows a total endowment of $15,325,000, and an expenditure for the year ending Sept. 30, 1913, of $658,431. Of this $519,440 were distributed in retiring allowances to professors, and $80,949 in pensions to their widows, a total of $600,390. Thirty-three allowances were granted during the year, making the total in force 403, the average annual payment to an individual being $1,703. The total distribution from the beginning has been $2,936,927. The educational work of the foundation was separately endowed in January, 1913, by a gift of $1,250,000 from Mr. Carnegie through the Carnegie Corporation of New York. This body, which is endowed with one hundred and twenty-five million dollars for "the advancement and diffusion of knowledge and understanding," has five ex-officio trustees, of whom one must always be the president of the Carnegie Foundation for the Advancement of Teaching.

The study of legal education has been begun by a first-hand inquiry into the bar examinations of every state, a special study of legal teaching by Josef Redlich, who came from Vienna for the purpose, and by a personal examination of each of the 160 law schools in the country. Plans for the study of engineering education are now being completed. The earlier educational work of the foundation is continued in the report by commendation of the present tendency of college entrance requirements toward both elevation and flexibility. The need for further improvement is shown by the fact that only 55 per cent. of the students now in our colleges are high-school graduates. The decrease in the number of medical schools in the country and the rapid improvement of the better schools are commented on with appreciation. A general study of the problems of the state regulation of higher education is illustrated by a detailed account of the recent crisis in educational affairs in Iowa.

Tennessee Reciprocity Report

Dr. A. B. DeLoach, secretary of the Tennessee State Board of Medical Examiners, reports that 17 candidates were licensed through reciprocity from Jan. 15 to Dec. 23, 1913. The following colleges were represented:

College	Year Grad.	Reciprocity with
Columbian College, Washington, D. C.	(1903)	Kentucky
Atlanta School of Medicine	(1911)	Georgia
Georgia College of Eclectic Med. & Surg.	(1912)	Georgia
Northwestern University	(1908) (1911)	Minnesota Georgia
Kentucky School of Medicine	(1896)	W. Virginia
Louisville and Hospital Medical College	(1908)	Oklahoma
University of Louisville	(1911) (1911)	Kentucky Kentucky
University of Maryland	(1909)	Maryland
University of Michigan, Dept. of M. & S.,	(1894) (1897)	Michigan Michigan
University of Pennsylvania,	(1907) (1908) (1911)	North Carolina Virginia Maine
Chattanooga Medical College	(1907)	Virginia
University of Nashville	(1900)	Mississippi

District of Columbia January Report

Dr. George C. Ober, secretary of the Board of Medical Supervisors of the District of Columbia, report the oral and written examination held Jan. 13-15, 1914. The number of subjects examined in was 8; total number of questions asked, 80; percentage required to pass, 75. The total number of candidates examined was 10, of whom 7 passed and 3 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Georgetown University	(1913)	85.3, 91.4
Howard University	(1913)	75.8
American Medical Missionary College	(1904)	78.4
University of Illinois	(1913)	83.4
Baltimore Medical College	(1913)	80.9
Jefferson Medical College	(1905)	76.8
FAILED		
Maryland Medical College	(1913)	70.8
College of Physicians and Surgeons, Boston	(1911)	68.7
Leonard Medical School	(1913)	62.2

Book Notices

Defective Ocular Movements and Their Diagnosis. By E. and M. Landolt. Translated by Alfred Roemmele, M.B., Ch.B., and Elmore W. Brewerton, F.R.C.S. Cloth. Price, $2. Pp. 99, with 27 illustrations. New York: Oxford University Press, 1913.

In this small volume the authors have succeeded in presenting the essential known facts of this important, and at the same time difficult, branch of ophthalmology. A great deal has been written on this subject, and in this book the authors have not presented any new facts or proposed any new theories, but have endeavored to group the facts which are absolutely necessary for the correct understanding of oculomotor affections, particularly those which are apt to be overlooked by the general practitioner, as a correct analysis of the various forms of oculomotor disturbances is of the highest importance in diagnosing the different diseases of the brain and nervous system. Not the eyes alone but the entire nervous system must always be taken into account in oculomotor affections. After a brief summary on the fundamental laws governing the normal eye movements, with the anatomy and physiology of the ocular muscles, a few pages are given to the practical application of prisms, and the remainder of the book is devoted to the pathology of the different forms of oculomotor disturbances with their symptoms and diagnosis. Contrary to the method usually adopted in text-books, of enumerating the various diseases and then describing their symptoms, the authors have done just the reverse, beginning with the symptoms and then leading up to the disease which causes them. It is really thus, as the authors state, that the problem presents itself to us in practice. The patient does not come with the name of his disease, asking for the symptoms; he relates his symptoms and we should from them diagnose the disease and deduce the nature and seat of the lesion. The section on the differential diagnosis of paralysis of individual ocular muscles is admirably stated. The classification of the different rotations of the eye as brought out by the double images is easily comprehended, especially if one has familiarized himself with Duane's table. The latter part of the book, which deals with the seat and etiology of the oculomotor affections, gives the essential facts of each case, so far as they are known, clearly and briefly. The authors are to be congratulated on having given to the busy ophthalmic surgeon this *multum in parvo*, which will serve him, as they say, not as a hand-book, but rather as a handy book.

Principles of Surgery. By W. A. Bryan, A.M., M.D., Professor of Surgery, Vanderbilt University. Cloth. Price, $4 net. Pp. 677, with 224 illustrations. Philadelphia: W. B. Saunders Company, 1913.

This book, dedicated "to the men I have taught," presents to the student, or practitioner in need of "brushing up," the fundamentals of surgery and especially surgical pathology in a simple, logical manner. The individuality of the teacher is reflected in his writings, at the same time he is fair in his dogmatism. While objecting to the so-called non-absorbable sutures, he admits their harmlessness in intra-abdominal work and also concedes the fact that catgut becomes an excellent culture-medium for bacteria. The chapter on inflammation is particularly complete. Its explanations really explain, and should be of great help to the busy practitioner. The dictum, "no anodynes until the diagnosis is clear and the patient has agreed to the employment of safe means for his relief," cannot fail to impress the student. In the chapter, in which the treatment of sepsis is discussed, the author warns that "purgation of an exhausted patient can prove quickly fatal. The only safe route of elimination should be by the kidneys, and the remedy is water." In the chapter on tetanus he omits to mention the use of magnesium sulphate injections, apparently favoring Bacelli's intravenous injections of phenol (carbolic acid). Absolute non-interference of anthrax lesions and reliance on serum treatment are plainly urged. In the chapter on wounds, the author teaches that infection develops more readily in contused wounds than in any other type, on account of extensive devitalization. One must object to his advising a thorough scrubbing of a second degree burn with brush, soap and water; such statements are not modern. He also fails to mention the "open-air" treatment of burns. The classification of tumors and the surgical pathology are an admirable summary of the entire subject as at present understood. Regarding uterine myomas the author correctly states that "the old belief that they disappear at the menopause is untrue and dangerous. The danger of malignancy, though small, must not escape us." Writing on sarcoma, he warns us that "many of the notions held by some of the profession are due to ancient teachings that have been handed down from generation to generation, without an attempt to correct them in accordance with the advances made by pathologic study and clinical observation of patients before and after treatment, and by our ability to make accurate diagnoses, microscopically, long before a clinical diagnosis could be vouchsafed. Hence much that is untrue is still accepted and occasionally acted on as true.

The Biology of the Blood-Cells with a Glossary of Hematological Terms. For the Use of Practitioners of Medicine. By O. C. Gruner, M.D., Pathologist to the Royal Victoria Hospital. Cloth. Price, $6 net. Pp. 392, with 75 illustrations. New York: William Wood & Co., 1914.

"This work is intended to serve as a companion to any of the larger text-books on hematology. Special stress has been laid on the close relationship between changes in the blood-forming organs and the blood-picture as the clinician sees it, and also on the minute morphology of the various blood-cells, whether sessile or free-floating."

In these days the study of the development of the various types of cell seen in the circulating blood is assuming increased importance, owing largely to the epoch-making studies of Pappenheim and his followers. The proper interpretation of the presence of unusual cells or of variations in the number and kinds of normal blood-cells in the blood-picture of any disease may be made only when a thorough knowledge of the origin and developmental cycle of such cells is at hand. Gruner has attempted to present his material in such a way that the reader is led by gradual steps to a complete familiarity not only with the origin and development of the various cells, but also with the hematopoietic mechanism which leads to the appearance of abnormal cells in the peripheral blood. That he has accomplished his object in a thoroughly convincing manner is evident from a perusal of the work. The subject-matter of the book is divided into seven chapters, on the primordial blood-cell, the red blood-cell, the lymphocyte, the large mononuclear leukocyte, the neutrophil leukocyte, phlogocytes, and the cystoplastic phenomena of blood-forming tissues. Each of these chapters is written in such a clear and concise manner that the reader has no difficulty in grasping the various points dealing with the developmental and morphologic characteristics of the cells discussed. The glossary of terms at the end of the book is very complete and deserves special mention and reference. This book is one which should be in the library of all who have an occasion to examine blood-smears, and should be carefully studied by those who wish to enlarge their knowledge regarding the interpretation of the blood-findings in various diseases. It gives a thorough and convincing exposition of the accepted biologic theories of the origin and development of the blood-cells.

Les techniques anatomo-pathologiques du système nerveux: anatomie macroscopique et histologique. Par Gustave Roussy, Chef des Travaux d'Anatomie Pathologique à la faculté de Paris, and Jean Lhermitte, Ancien Chef de Laboratoire à la Faculté de Médecine de Paris. Cloth. Price, 5 francs. *Pp. 255. Paris: Masson et Cie, 1914.*

This little book contains a selected list of methods, which have been personally tested by the authors, for the gross and microscopic study of the nervous system in both normal and pathologic conditions. The selection is in general judicious and the directions clear; there are some new methods described and some remarkable omissions (for instance, no mention whatever of the Golgi method). It is a practical working manual, adapted for the needs of the beginner. "It is not a book for the library; its place is on the laboratory table beside the fixing fluids and stains."

Miscellany

Proteoses and Fever

Experiments calculated to show a relationship (should any such relationship exist) between the injection of proteoses into the animal organism and the development of fever symptoms are reported by Gibson in the *Philippine Journal of Science*, viii, B, p. 475. These experiments were undertaken on account of the conflicting views and theories of previous workers and because of their bearing on "peptone intoxication" and anaphylactic shock and the relation of these to the development of fever symptoms.

Von Pirquet and especially Friedberger have developed the theory that the phenomena of anaphylaxis play an essential part in the production of the symptoms observed in the contagious diseases. The symptoms declare themselves when the antibodies, elaborated by the organism, begin to react with the microbes. Mita and Friedberger have shown a relationship of fever in infections to anaphylaxis. These authors assert that the injection of minute amounts of foreign protein into guinea-pigs sensitized to that protein produces a marked rise in temperature following the characteristic fall. Successive injections yield temperature curves very similar to those of infectious fevers. In anaphylactic shock the symptoms resemble those which obtain during the intoxication resulting from intravenous injection of proteoses. There seems to be evidence also that the formation of anaphylatoxin is associated with the cleavage products of the protein antigen. Pyrexial action is asserted for proteoses prepared in the laboratory as well as for those elaborated by bacteria, both intracellular and extracellular substances so elaborated. If the extracellular substances are precipitated by alcohol or ammonium sulphate and injected into guinea-pigs, they excite fever. Such injections are more pyrogenic for tuberculous animals than for normal ones. When the proteoses are prepared in the laboratory they are not so pyrogenic in their action as those of bacterial origin. Klemperer considers that the cause of fever in such cases is not the introduction of proteoses but rather impurities of bacterial origin. Recently, Bordet has questioned the identity of anaphylaxis and "peptone" intoxication. He concludes from his experiments that there is not just ground for the theory of the production of poison by digestion and disintegration of the antigen. Loewit also believes that there is insufficient evidence for believing that anaphylactic shock and the "peptone" shock are identical. Auer and Van Slyke also bring forward additional evidence that the anaphylactic shock is not due to proteoses. The question of importance at this point is, whether the symptoms of "peptone" intoxication are due to the proteoses injected or to some substance which is physiologically active. Pick and Spiro have concluded that these effects are due to some substance of animal origin. Underhill verified their experiments. With this situation before him, Gibson considers the possibility of a substance other than that injected being responsible for the pyrexial symptoms following an injection of proteoses and their relation to anaphylaxis. Great care was taken in the preparation of the proteoses. They were made from four times reprecipitated caseinogen, recrystallized edestin and thoroughly washed pig fibrin. Rabbits and guinea-pigs were used as experimental animals. They were handled as little as possible, fed well and injected subcutaneously with aseptic precautions. Records of all animals, as to weight, sex, date of injection, temperature at time of injection and range of variation for from five to ten days were kept. Only two out of twelve experiments on guinea-pigs gave a definite pyrogenic reaction. The preparations mentioned above do not seem to be consistently pyrogenic for guinea-pigs; but in the experiments on rabbits no evidence of fever resulted from the proteose injections. Since there was practically no pyrexial effect, no relationship between anaphylactic shock and "peptone" intoxication was discovered. "It would seem then, that the primary cleavage products of pepsin-hydrochloric digestion, when prepared without drastic treatment, from purified and well-characterized proteins, never have more than a slight pyrogenic effect when injected subcutaneously into rabbits and guinea-pigs. Any temperature rise, if present, is insufficiently pronounced to permit a direct inciting rôle to be ascribed to such proteoses in the production of the severe naturally occurring fevers."

Drying Cultures of Lactic Bacilli

A press bulletin of the U. S. Department of Agriculture says that the general interest in fermented milks has stimulated the production of various kinds of tablets and capsules which are supposed to contain lactic-acid organisms in such quantities that the culture can be used to start fermentation in milk or to inoculate the digestive tract by direct consumption. These cultures, as well as those for butter- and cheese-making, are of value only when they contain the desired organism free from contamination and sufficiently active to start the fermentation before too great accidental contamination develops. The ideal form for such cultures is a dry state, sufficiently active to produce rapid growth when added to milk, and yet so dormant that the organism can be held a long time without losing its activity. This is difficult to attain and many dry cultures are practically inert. The most successful commercial cultures are sold in liquid form. The department has devised a method of preparing dry cultures which preserves to the greatest extent their activity. It consists in freezing the cultures and then drying them over sulphuric acid in a vacuum approximating 0.01 mm.. The activity of the dried cultures diminishes more rapidly the higher the moisture content. The loss in activity is slow at 0 C. (32 F.) and is more rapid as the temperature rises. Cultures of lactic acid bacteria at 30 or 37 C. (86 or 98.6 F.) become inactive in a short time. The *Bacillus bulgaricus* made by the freezing-vacuum method is active and curdles milk in twenty hours at 37 C. in the ratio of 1:100,000. Yeasts do not survive the process, as the powders obtained were very feeble.

Value of Vital Statistics

As an argument against the value of vital statistics as ordinarily gathered, E. Goodman, in the *California State Journal of Medicine*, quotes again the statement frequently made that fully 50 per cent. of ante-mortem diagnoses are disproved by post-mortem findings. He says that even if violent and accidental deaths, deaths from occupational diseases, from specific infections and other obvious causes can be established beyond a doubt, yet the great number of doubtful causes vitiates all results. He asserts that necropsy is the only thing that stands between vital statistics as a guess and vital statistics as a science. While the desirability of establishing the exact causes of death in all cases by necropsy is obvious, yet it cannot be agreed that the value of the "bookkeeping of humanity" depends wholly on this. Most cases of infectious disease, including tuberculosis and typhoid fever, are correctly diagnosed, as is cancer in the fatal cases. In these diseases it is highly important that statistics be gathered in order that the large view of their causation and propagation may be obtained and preventive measures devised. Many of the obscure conditions subject to frequent errors in diagnosis do not occur in a large number of cases. Accurate figures in such conditions as gastric ulcer, gallstones, nephritis and some of the heart conditions are a valuable aid in arriving at a correct conception of their general determining causes, but in the conditions named above, in the occupational diseases and in the accidental causes of death, mortality and morbidity statistics are most valuable, and these are now determined, when collected at all, with sufficient accuracy. To determine merely the birth- and death-rate is of great importance, and justifies any efforts to obtain universal and accurate registration. The verification of the causes of death by necropsy in every instance is out of the question, but to say that lack of this vitiates the value of all vital statistics is not a tenable statement.

Authority of Superintendents to Employ Physicians to Render Services to Injured Employees—Summoning of Aid for Third Persons

(Ghio vs. Schaper Bros. Mercantile Co. (Mo.), 163 S. W. R. 551)

The St. Louis (Mo.) Court of Appeals says that the mere office of superintendent does not imply authority to contract for medical and surgical services rendered to third persons injured in its employ. But it is well settled that a superintendent may contract for medical and surgical services rendered to a third person, injured in the employ of the company, if it appears he possesses, and is accustomed to exercise, broad and comprehensive authority with respect to the conduct of the company's affairs in a general way.

Ordinarily, if one person requests another to perform beneficial services for him, and accepts and appropriates the benefits, the law implies a promise to pay the reasonable value. But this is because the services are of value to the person requesting the performance, and because, too, the law will presume that every person intends to pay for that which is wrought, at his instance and request, to his benefit. It is not the same, however, when one person merely calls a physician or a surgeon to attend a third person, for the dictates of humanity frequently induce one to do this, and, indeed, it may be the sick or afflicted person is at the time unable to speak for himself. Therefore it is the rule of decision that unless the relation of the person making the request is such as to raise the legal obligation on his part to call a physician and pay for his services, the law will not imply a contract to do so on a mere request.

Though such be true, however, it is not essential that there shall be an express promise to pay, even when one calls a physician to attend a third person with respect to whom no legal obligation obtains, if it sufficiently appears from the facts and circumstances in proof that the physician intended to charge for his services, and the person requesting him to perform the service intended to pay therefor. The distinction between an implied contract and an actual contract, though not an express one, which may be found by the jury from the facts and circumstances, as when it appears one party intended to charge and the other intended to pay, is recognized every day in the administration of the law. So, in this case, though no one in express words promised to pay the plaintiff for his services, rendered to an injured employee of the defendant, he might nevertheless recover on contract if the jury found as a fact that he rendered the services at the request of the defendant, with an intention on his part to charge, and that the defendant intended to pay therefor.

Physician's Willingness to Commit Crime Not Punishable—Nature of Rights—Inadmissible Evidence—Construction of Statute

(State ex rel. Spriggs vs. Robinson et al (Mo.), 161 S. W. R. 1169)

The Supreme Court of Missouri, Division No. 2, reverses a judgment of the circuit court sustaining the State Board of Health in suspending the relator or appellant from the practice of medicine and surgery in that state for a period of one year. The charge on which he was suspended was that he was guilty of "unprofessional and dishonorable conduct," in that he was willing to commit a criminal abortion. He had advertised in a local newspaper: "Practice limited to diseases of women and surgery. Office and private hospital," etc. The state statute under which he was suspended provides that the board may revoke licenses for, among other things, producing a criminal abortion, but the specifications in the act were not intended to exclude all other acts for which licenses may be revoked.

The court says that the appellant through his license to practice medicine, and through his ability and industry, had become possessed of at least a valuable privilege—perhaps a property right—which had been suspended by the action of the respondents for his alleged violations of the laws of the state; that it was not a mere shadowy privilege which might be revoked regardless of whether the possessor had violated the laws of the state, and the court found nothing in the brief of the attorney-general to intimate that the conviction and suspension of the appellant could be sustained on the advertisement which he published. Nor was hearsay evidence of another physician to the effect that the appellant bore the reputation of being a criminal abortionist sufficient.

The statute, in so far as it authorizes the revocation of licenses of physician, is highly penal and cannot be expanded or enlarged beyond its letter or spirit. Its general specification is directed solely against certain undesignated acts, not against evil thoughts or a willingness to perform wrongful acts. However reprehensible it may be for a physician to entertain a desire to commit abortion, his license cannot be revoked therefor unless by a written statute his desires are made the ground for subjecting him to that penalty.

Liability of Chartered Sewage Disposal Company for Maintaining a Nuisance

(State vs. Collingswood Sewerage Co. (N. J.), 89 Atl. R. 525)

The Supreme Court of New Jersey affirms a conviction of the defendant of maintaining a nuisance. The court says that the nuisance complained of was that, in the conduct of its sewage disposal plant, it permitted the generation of unpleasant and offensive odors, to the injury and discomfort of the community. It was a corporation, chartered under the Act of 1898 to collect, treat and dispose of sewage. To meet the state's case, the defendant took the position that, because it had secured the approval of its plans for the building and location of its plant, and had in every respect complied with all the requirements of the State Sewage Commission and the State Board of Health in the construction and operation of its plant, therefore it was immune to an indictment, even though there was faulty construction and operation of the plant which gave rise to offensive smells. But the court thinks the position taken by the defendant untenable. The legislature, in conferring on the defendant the privilege to treat sewage, did not grant with it a license to maintain a nuisance. Nor did the fact that the defendant constructed part of its plant under plans approved by the State Sewage Commission absolve it from liability for maintaining a nuisance. When the defendant discovered that the nuisance arose from faulty construction, its plain duty to the public was to amend such faulty construction, and not to go on continuing the nuisance. As there was some evidence from which the jury might properly have found that the nuisance complained of was the result of both a faulty construction and careless operation of the plant, the court properly refused to direct a verdict for the defendant. Nor was there error in a refusal to permit the defendant to prove the cost of the plant and that it was not a profitable concern; that it did not meet fixed charges, etc. The element of cost did not enter into the inquiry in any aspect of the case. No matter how much the plant might have cost, or how unprofitable it might be, neither element was sufficient to absolve a defendant from maintaining a nuisance arising from faulty construction or negligent operation of the plant. Moreover, the theory that, because the plans were drawn by engineers in the employ of the State Board of Health (which board, under an an act of 1908 amended in 1909, was vested with the powers and duties of the State Sewage Commission), recognized and approved by the board, therefore there could be no faulty construction, was palpably fallacious. When a plant is put into active operation and it is discovered that offensive odors are generated, which would not be the case if the plant were properly constructed, it is going to an unwarranted length to ask the court to assume that, because the plant was constructed under the approval of the State Board of Health, on plans of its engineers, therefore, as a matter of law and fact, there could be no faulty construction of the plant, and any nuisance generated thereby is a necessary incident of the business authorized by the legislature.

ASSOCIATION OF AMERICAN PHYSICIANS

Twenty-Ninth Annual Meeting, held at Atlantic City, N. J., May 12 and 13, 1914

(Continued from page 1748)

Splenectomy for Pernicious Anemia

Drs. Warren Coleman and John A. Hartwell, New York: Splenectomy was performed as a last resort. Ten weeks later neosalvarsan was administered. The use of neosalvarsan makes it impossible to draw any conclusion as to the effects of the splenectomy except in the interval before its administration. In this interval there was no evidence of more than temporary improvement. At the present time, April 24, six months after the operation, the patient, while looking better and feeling better, is just beginning to sit up.

Studies in Pernicious Anemia

Dr. Herbert C. Moffitt, San Francisco: The results from splenectomy have been variable. In eight cases death resulted either immediately or soon after operation. A number of other cases have not been improved. In still other cases reported in the literature, surprising improvement has taken place. In my case paresthesia, which was obstinate before operation, disappeared at once afterward. There are other striking changes in the blood regeneration which follow soon after operation in many cases.

Studies in Experimental Arteriosclerosis

Dr. I. Adler, New York: Dogs were injected, partly intravenously, partly subcutaneously, with various substances, such as epinephrin, nicotin, lead, diphtheria toxin and pure cultures of different species of bacteria, all with absolutely negative results. In a further set of experiments, dogs were fed with a number of substances, under varying conditions. and it is believed that some positive results were obtained, so that the aorta in some cases showed lesions which both macroscopically and histologically were closely analogous, if not absolutely identical with human arteriosclerosis.

Case of Recurrent Fever in Aortic Aneurysm

Dr. Alexander McPhedran, Toronto: A woman, aged 36, of irregular life and habits, complained of pain in the right chest. She had recurrent fever about every seven or eight days. The aortic arch was dilated and showed a pulsating aneurysm in the first left intercostal space. The temperature became normal and remained so and her general condition improved very much. She was treated with iodids, mercury and salvarsan.

Certain Tests of Renal Function

Dr. W. S. Thayer, Baltimore: When I have been able to correlate the anatomic and clinical observations, they have tended to fortify my previous opinion that the phenolsulphonephthalein test is a reliable one of considerable diagnostic and prognostic value, especially in the study of chronic nephritis.

DISCUSSION

Dr. Charles F. Withington, Boston: A man, brought into the hospital unconscious, showed unmistakable evidences of acute nephritis. There was a history of convulsions and of coma. Twenty-four hours after the patient was brought in the phenolsulphonephthalein output was 70 per cent. His condition proceeded to clear up and he went out about two weeks after he was brought in, showing a surprising phenolsulphonephthalein output, although manifesting signs of *nephritis.*

Dr. Joseph L. Miller, Chicago: A man came to the hospital, not very ill, in whose case a definite diagnosis of chronic interstitial nephritis was made. He was passing 2,000 c.c. of urine a day. We could not get a trace of phenolsulphonephthalein through in two hours. In forty-eight hours and up to the time he went into coma, he passed a large amount of urine, and at the end of forty-eight hours he went into coma and died. Necropsy showed a high degree of interstitial nephritis.

Syphilitic Nephritis

Dr. Alfred Stengel and Dr. J. Harold Austin, Philadelphia: We have examined the urine with the polarizing microscope 58 times from 46 cases. Of these 46 cases, 23 showed nephritis with an abundance of albumin and casts in the urine. Of these 23 patients, 6 had positive Wassermanns, 3 had strong presumptive evidence of syphilis, but no positive Wassermanns;14 had not the slightest evidence of syphilis. The 6 cases with positive Wassermanns all showed lipoids in the urine. The rest of the 46 cases studied were made up in part of nephritis cases of the interstitial or arteriosclerotic types, with only traces of albumin in the urine, and a few hyaline and granular casts, some with syphilis and some without, any number of syphilitic cases with no nephritis, and any number of control cases with neither syphilis nor nephritis. None of these cases showed lipoids in the urine. One of the six syphilitic cases with nephritis showing lipoids in the urine had not received any mercury.

In order to determine whether or not the common experimental degenerative nephritides of animals would be associated with lipoids in the urine, three rabbits were given uranium nephritis and one dog a chromate nephritis. The four experiments were negative; no lipoids were found in the urine. Further experiments with mercurial nephritis, phosphorus and chloroform lesions and syphilitic inoculations are in progress.

The Pathologic Evidence of the Relationship Between Gastric Ulcer and Gastric Carcinoma

Dr. Louis B. Wilson, Rochester, Minn.: Any existing disagreement as to the relationship between gastric ulcer and gastric carcinoma depends on (1) failure to understand the pathologic data, (2) inappreciation of the bearing on the clinical data, or (3) failure to appreciate the correlation existing between the two. Small gastric ulcers are usually simple, and large cauliflower-like cancers usually show little evidence of previous ulceration, but between these two lies a large group of ulcerated lesions of the stomach, some of which are ulcers only and others of which resemble ulcers in all respects, except that in addition they also show cancer. So far as the pathologist is concerned, he cannot positively distinguish, in many such specimens, between simple ulcer and ulcer plus cancer, except with a microscope. When, in such a specimen showing cancerous areas, no cancer-cells are found in the base of the ulcer, one is warranted in assuming that the ulcerative lesion preceded the cancer.

The Etiology of Some of the Infective Tropical Granulomas

Dr. Richard P. Strong, Boston: Among the infective granulomas which occur more commonly in certain tropical countries and which are perhaps of unusual interest from an etiologic point of view, are verruga peruviana, ulcerating granuloma of the pudenda, and frambesia. Verruga peruviana and Oroya fever have been considered to be merely different stages of the same disease, Oroya fever having been regarded as the initial stage of the granulomatous verruga stage. The two diseases, however, are quite distinct and have a very different etiology. Verruga peruviana is due to a virus which may be transmitted to some of the lower animals, while Oroya fever owes its origin to a parasite of the red blood-corpuscles. The two diseases also have a very different pathology. The etiology of ulcerating granuloma does not seem to be definitely determined.

AMERICAN DERMATOLOGICAL ASSOCIATION

Thirty-Eighth Annual Meeting, held in Chicago, May 14-16, 1914

(Continued from page 1749)

Epithelioma of the Hand Following Traumatism, Resembling a Granuloma

Dr. Howard Fox, New York: The patient was a man of 48, whose previous history showed only an attack of measles when a child, and an attack of "blood-poisoning" in the left wrist, for which incision was made, and which healed at the end of sixteen weeks. Syphilis was denied. During the summer of 1911 he was bitten on the back of the right hand by a horse, which injury caused an open wound at the junction of the fifth metacarpel bone with the carpus, which healed in the course of two weeks. Five or six weeks later an open sore again appeared on the back of the right hand, which gradually extended in area and became red and swollen, with discharge and crust formation. When first seen, the right hand showed the characteristics of ordinary senile skin. The entire dorsal surface was swollen, edematous and tender, the swelling extending to the wrist and first phalanges. On this area were serpiginous, rather sharply bordered ulcerating and crusted lesions, extending from the knuckles to the proximal ends of the metacarpal bones. The central portion was covered with epidermis. By pressing on almost any portion of the back of the hand a considerable amount of thick, yellowish pus could be expressed. The clinical picture was that of a granuloma due to tuberculosis, blastomycosis, actinomycosis or possibly syphilis, complicated by an extensive suppurating cellulitis. Wassermann reaction was negative. A biopsy was then made, which showed the presence of a most typical squamous-celled epithelioma. Patient refused operation, and six Roentgen-ray exposures were given. He was also treated by wet dressings of potassium permanganate. Examination of the chest showed some coarse râles, slight dulness and diminished breathing. A roentgenogram of the chest indicated involvement from the level of the fifth dorsal down to the lower border of the ninth rib, the irregularity of the shadow indicating carcinoma. The patient lost weight and became cachectic. Dysphagia steadily increased, and after gastro-enterostomy for its relief the patient died.

Epithelioma of the hand is a comparatively rare condition, and in the vast majority of the cases occurs on the dorsal surface. In spite of being histologically, as a rule, a malignant type of cancer, it runs a slow and relatively benign course, seldom invading the lymphatic glands. The majority of cases develop on a basis of chronic inflammatory tissue; few arise after a single traumatism.

DISCUSSION

Dr. Alfred Schalek, Omaha: I had a case much like the one reported, but in my case the growth occupied the whole dorsum of the hand. I suspected malignant disease at first. I did not think of epithelioma because I had never seen a case of epithelioma in the hand. There was extreme pain. The growth was excised, and later a skin graft used, which was followed by recurrence. The patient was referred to a surgeon, who amputated the arm. After that I heard nothing more from him. In my case the process certainly was not benign. It looked to me to be very malignant.

Dr. W. A. Pusey, Chicago: I have seen a considerable number of epitheliomas on the back of the hand. My experience in general corresponds with Dr. Fox's, that such epitheliomas are relatively not very dangerous; but this has set me to thinking of one thing during the last few years, namely, why epitheliomas on the back of the hand occurring in Roentgen-ray skins are so excessively dangerous. I think it is a general fact that they are very liable to metastasis, and I would like to know why these lesions are dangerous, while ordinary ones are not. I have seen only one epithelioma on the palm, and that was an exceedingly interesting case.

Dr. M. B. Hartzell, Philadelphia: I have seen three or four patients in whom epithelioma has followed immediately on a slight injury. One occurred on the end of the nose of a woman between 50 and 60 years of age; a scratch, which never healed, was followed within a few weeks by a typical epithelioma. In another case the epithelioma occurred on the inner surface of the lip, following a traumatism inflicted by a dentist. I can also recall two cases of carbuncles on the back of the neck which were followed immediately by epitheliomas; that is, the wound left by the carbuncle never healed, and epithelioma developed on that site. Perhaps my experience has been unusual.

Dr. Martin F. Engman, St. Louis: The case of Dr. Fox seems to illustrate the theory of Ribbert uniquely, in which the normal epithelium through an ulcerating surface is misplaced and separated from its kindred, and thus undergoes atypical physiologic functionating, and rather quickly develops into an epithelioma. We see quite a number of cases of epithelioma of the back of the hand, but they usually originate from keratoses. I have seen several cases following Roentgen rays, and one case, I think, was fatal. This seems to be due to the poor regenerative qualities of the connective tissue, possibly, and the poor condition of the vessels. In a large proportion of these cases the epithelioma is preceded by secondary degeneration of the connective tissue, as found by White.

Dr. G. W. Wende, Buffalo: I have had a case of epithelioma on the palmar surface of the hand, following an injury. It developed soon after the traumatism, and grew rapidly. The course, from beginning to end, was less than a year and a half in length.

Dr. Udo J. Wile, Ann Arbor, Mich.: I think that attention might be drawn to the one notable exception, at least, to the relatively benign nature of epithelioma of the extremities. A number of cases following the ingestion of arsenic preparations have been reported. A few years ago, in looking up the literature, I was struck by the large number of arsenical growths, all of which were fatal.

Dr. Sigmund Pollitzer, New York: I think that the class of cases which forms the subject of Dr. Fox's paper may well be brought under that group of epitheliomas which are the result of misplacement of the epithelial cells, caused by the trauma. In this respect this class of cases does not differ materially from another class of epitheliomas that occur commonly as the result of a nevus, with cellular proliferation. I have seen several cases of nevi which depend on cellular inclusions, as moles and pigmented moles that have been treated by cauterization by one method or another, and I think that it is a bad practice. A cellular inclusion nevus should be treated like an epithelioma, or let alone. I should like to emphasize that point. Ninety-nine times out of a hundred nothing happens, but in the last case, if a few cells are left behind, they are subjected to terrific irritation from the treatment, and are apt to degenerate into a malignant process.

Dr. Henry H. Hazen, Washington, D. C.: I have had the opportunity of going over one thousand cases of epithelioma of the skin with Dr. Bloodgood, at Johns Hopkins Hospital. In that series forty or fifty originated in the limbs. In from two to ten years absolutely every case of prickle-cell epithelioma in which the glands were not taken out developed metastases, one or two as late as ten years. These cases were all proved malignant by microscopic examination. When we have a prickle-cell epithelioma, we always should excise the draining glands, in addition to taking out the epithelioma itself. We ought also to be careful about our method of doing biopsies on prickle-cell tissues. We leave both the lymphatics and blood-vessels open, and there is a good chance for any cancer-cells to escape into those vessels. We should use a dull knife, and if we cannot do that the wound should be immediately cauterized.

Dr. W. T. Corlett, Cleveland: My experience may have been unique, but next to the epithelioma of the face, I have encountered epithelioma of the back of the hand most frequently, and in the latter cases I have been impressed with the frequency with which metastases have occurred. I have attributed that to the fact that epithelioma on the face is usually a conspicuous lesion and relief is sought at an early time, whereas an epithelioma occurring on the hand is usually less conspicuous, and therefore is liable to be neglected.

Dr. W. A. Pusey, Chicago: I should like to question the accuracy of any statistics to the effect that every case of epithelioma of the back of the hand had metastases. I think from my experience it is certainly extraordinary and not usual. I should also challenge the statement that every epithelioma of the back of the hand should be followed by extirpation of the lymphatics. I do not think it is common sense or good or necessary surgery.

Dr. Henry H. Hazen, Washington, D. C.: I said prickle-cell epitheliomas, and about 80 per cent. are prickle-cell.

Dr. Howard Fox, New York: Dr. Engman referred to the short time between the traumatism and the development of the epithelioma. I do not think that six months is a very short time, but I just mentioned the traumatism as a suggestion; I think it would be impossible to prove that that traumatism with the resulting scar was the actual cause of the epithelioma. In one of the cases reported in the discussion the epithelioma appeared ten years afterward in the scar resulting from the bite of an animal. From the literature I have found that epithelioma occurs on the sole of the foot a good deal more often than on the palm of the hand, and I think that some of these cases have started in perforating ulcers. Certainly, the majority of cases of epithelioma of the extremities arise on a basis of some chronic inflammatory process, a lupus or a fistula, in connection with an osteomyelitis or a chronic dermatitis or a chronic ulcer of some sort, and a relatively small number arise on apparently normal skin. In regard to the malignancy of the cases occurring after Roentgen-ray work, according to the statistics of Brunn and Volkmann the most malignant type of epithelioma is that which develops on wheals and moles, congenital or those which appear later in life.

(To be continued)

MEDICAL SOCIETY OF THE STATE OF NEW YORK

One Hundred and Eighth Annual Meeting, held in New York City, April 28-30, 1914

(Concluded from page 1751)

Cystitis Colli or Trigonitis

Dr. Henry D. Furniss, New York: Before the use of the cystoscope, these patients were all considered neurotics. Authorities have attempted to separate these cases of cystitis colli, referring to them as the non-inflammatory and to the other as the inflammatory type. In the non-inflammatory type the trouble at the neck of the bladder may be due to pressure from a retroverted uterus, a pelvic growth, cystocele or any other cause of pelvic congestion. I am of the opinion that these are coincident infections, and very seldom is there any other form of cystitis colli than that due to infection. The two principal infections are gonorrhea and colon bacillus. The best results are obtained by local treatment to the trigon with from 3 to 8 per cent. silver nitrate. The silver nitrate is neutralized by the urine.

DISCUSSION

Dr. John O. Polak, Brooklyn: I have found these infections more frequent than previous writers have been inclined to consider them. For several years I have discarded vulvar pads on these patients and have found a direct relation between the number of infections, sufficient to convince me that the vulvar pads should be discontinued. The intestinal tract is very apt to soil the vulvar pads and the wound is infected frequently from the vulva and thus infection of the genital tract results. I have found post partum a large number of cases of cholecystitis, the majority of them having subsided under the expectant plan of treatment to fall later into the surgeon's hands for operation for chronic gall-bladder inflammation. I have seen many cases of appendicitis during pregnancy associated with colon bacillus infection of the kidney; I have seen a number of cases of appendicitis in the puerperium. I have yet to see a case, however, of colon bacillus infection of the kidney that has necessitated the interruption of pregnancy.

Dr. Reginald M. Rawls, New York: I have gone over the reports of about four hundred cases in the literature and I find that in the great majority of colon bacillus infection cases recovery occurs spontaneously under conservative treatment. I would not be so radical as Dr. Davis in recommending operation in so many of these cases.

Dr. Paul Pilcher, Brooklyn: One of the most dangerous things we can do is to resort to surgery on a kidney whose pelvis is infected, and if we are going to cut a kidney in the presence of infection we should end in the majority of cases by taking the kidney out. Our results in the cases of pyelitis in pregnancy have been very good and in none have we operated on the kidney. We have drained many of them. As to infection of the intestinal tract from colon bacillus, Dr. Davis said appendectomy had been done in a number of these cases. I have found the greatest advantage of a permanent nature to come from appendicostomy rather than from appendectomy. As to infections at the neck of the bladder, I am not quite willing to call them cystitis colli. We seldom see the bladder infected in these cases. It is more a disease of the urethra than of the bladder. The treatment is applied to the neck of the bladder and the urethra rather than to the bladder itself.

Dr. Rosalie S. Morton, New York: I believe that this condition is one which is frequently overlooked. I have had under my care a young woman who has suffered for four years with this infection as a result of tears at the time of an instrumental delivery four years ago. If the attention of the profession were called to the frequency of this infection, I am sure that many of these patients would be saved from years of invalidism.

Methods of Treatment of Puerperal Infections Which Have Given Improved Results

Dr. Raleigh R. Huggins, Pittsburgh, Pa.: One hundred and twenty-five cases of infection following abortion after the second month of delivery have been treated in a conservative manner as far as the inside of the uterus is concerned, except when firm contraction of the uterus was not present, or when it could not be secured by the use of strychnin or ergot, or when the uterine cavity was firmly packed with iodoform gauze. This was done for the purpose of securing firm contraction if the uterus had not been emptied to facilitate the expulsion of its contents. The satisfactory use of magnesium sulphate locally in erysipelas led me to try it in the treatment of puerperal infection. At first it was given in a 1 per cent. solution of saline, about 30 grains at a time. Later it was learned that much greater quantities could be given safely if given slowly. Dr. Harrar of New York has used 250 grains without any alarming effects. Distilled water has been used instead of saline, and there have been fewer chills following its administration. There have been no accidents from its use, and I have given it more than 150 times. It is not bactericidal, but the tissues are stimulated to greater resistance.

The most rational treatment in the beginning of every case of sepsis starting within the uterus is based on a keen appreciation of the pathology. The most important indication is to secure firm contraction of the uterus. The second factor is a healthy respect for Nature's protected zone, in this way limiting the spread of the infection. Good drainage is also an important factor and is secured by placing the patient in a sitting position. Active general measures, such as attention to diet, elimination and fresh air are the important factors in the treatment of puerperal infection.

DISCUSSION

Dr. James A. Harrar, New York: I have used the intravenous infusions of 2 per cent. solution of magnesium sulphate in freshly distilled water in a number of cases of streptococcic toxemia, and in twelve cases of streptococcic bacteriemia proved such by repeated positive blood-cultures. Dr. Huggins has been extremely fortunate in securing such a large number of bacteriemias on which to test out the blood, and his results have certainly been extraordinary. In a large service, such as that at the Lying-In Hospital, of over 5,000 puerperal women a year including infected post-partum cases sent in by doctors and midwives, we have had in three years but 12 cases of bacteriemia in which to use the injections. That bacteriemia is more often suspected clinically than is proved by blood-cultures was demonstrated by our former pathologist, Dr. J. E. Welch. In 176 cases referred for blood-cultures prior to 1908, he secured positive cultures in but 46. Of these 46, 43 died under ordinary methods of treatment. Dr. Meltzer warns against the depression of the respiratory centers by magnesium sulphate, but in considerably over a hundred intravenous injections of from 200 to 400 c.c. of a 2 per cent. solution of the salt I have seen no toxic effects of any kind.

Dr. Samuel J. Druskin, New York: In the cases under discussion the blood-vessels extending to the mucous lining are filled with clots, but the middle and outer layers are not. We also find the same reaction in the normal uterus. These clots are soft and have a tendency to break down. It has been demonstrated that the chorionic villi penetrate the mucous membrane, split the inner-muscle fibers and bundles, and there is penetration of the blood-vessels near the inner surface of the uterus. The blood-vessels react by hyaline degeneration, and there is a tendency toward splitting of the coat of the blood-vessel. The effect of this is that when the uterus contracts after parturition, the inner muscular layer does not close up and press the blood out of the blood-vessels. The blood-vessels themselves, and even arteries do not react as they normally do, and they have a tendency to become thrombosed. It would appear that the condition is not primarily an infection due to micro-organisms, but that we have first closure of the blood-vessels due to thrombi which later on become infected.

11 *Id. III. Stimulating Splanchnic Nerves. W. B. Cannon and W. L. Mendenhall, Bosotn.
12 *Id. IV. Pain and Emotional Excitement. W. B. Cannon and W. L. Mendenhall, Boston.

1. **Relation of Pituitary Body to Growth.**—Wulzen found that the growth of young fowl is retarded by the addition to the diet of fresh, unmodified anterior lobe of ox pituitary. This is shown both in body-weight and in length of the long bones. Involution of the thymus accompanies this retardation and may bear a causal relation to it. These effects are more marked in the males than in the females.

2. **Protective Rôle of Nascent Oxygen.**—The fact that pepsin and trypsin are oxidized by nascent oxygen and that the mucosa of the stomach and intestine possesses intense oxidative properties the Burges claim may be used to explain the protection of these organs from self-digestion during life; and the fact that diastase is destroyed by nascent oxygen offers an explanation of the observation that the amount of this enzyme is decreased during the day and increased during the night in plants. The fact that the autolytic enzymes are destroyed by nascent oxygen and that the tissues possess oxidative properties would seem to justify the assumption that normally there is a balance between the oxidative and autolytic processes in the living tissues. The fact that in certain pathologic conditions where autolysis is increased the oxidative processes are decreased is in accord with this assumption.

3. **Factors Influencing Gastric Hunger Contractions.**—The effects of smoking on the gastric hunger contractions were first studied by Carlson and Lewis in the case of a young man with a permanent gastric fistula. In his case smoking (cigars) invariably led to inhibition of the hunger contractions. But the man was not an habitual smoker, and the authors suggest that it is therefore possible that the results obtained on him were simply due to the condition of nausea or disgust that smoking usually produces in the novice and hence not applicable to persons used to smoking. The tests have been repeated on several habitual smokers.

In so far as smoking influences the gastric hunger contractions, this influence is in the direction of inhibition. This inhibition appears to depend on the intensity of stimulation of the nerve endings in the mouth, a cigarette or "mild" cigar causing only slight inhibition, while a "strong" cigar or pipe causes complete and prolonged inhibition even when the gastric hunger contractions are at their maximum. If the cigar or pipe causes very strong stimulation of the nerve endings in the mouth, the inhibition of the hunger contractions may continue from five to fifteen minutes after the cessation of the stimulation. Thus even a brief period of smoking may suppress an entire hunger period.

The subjective sensation of hunger is diminished or abolished parallel with the gastric hunger contractions. But it seems to the authors that even a "mild" smoke diminished the sensation of hunger rather more than one might infer from the slight depression of the contractions. This they believe, is probably due to the deviation of attention, the smoking acting partly as a "counter irritant." Smoking inhibits the gastric hunger contractions. It is practically certain even in the absence of direct experiments that moderate smoking does not inhibit the gastric movements of digestion. The reason for the difference in the action of the same condition on the empty and on the filled stomach is not clear from present data.

Experiments with constriction of the belt were made on three normal men. The tests were made with the subject standing up, sitting and lying on the back, and at all stages of the gastric hunger contractions. Strong contraction of the abdominal belt leads nearly always to inhibition of the gastric hunger contractions of weak or moderate strength, lasting from five to fifteen minutes. When the gastric hunger contractions are strong (the middle of a hunger period), constriction of the belt never causes complete inhibition. When the gastric hunger contractions are at their maximum in rate and amplitude, as is ordinarily the case near the end of a hunger period, no amount of belt constriction seems to influence the contractions. All three subjects agreed that the belt constriction appeared to diminish or interfere with the hunger sensation to a greater extent than seemed warranted from its effect on the hunger contractions. The authors state that belt constriction causes gastric inhibition, not by direct pressure on the stomach, but by direct stimulation of inhibitory nerves, or by mechanic (or sympathetic) stimulation of the adrenal glands, but through long reflexes.

4. Nervous Control of Gastric Hunger Mechanism.—According to Carlson moderate muscular activity (walking) has no direct influence on the gastric hunger mechanism. Intense muscular activity (running) inhibits the hunger mechanism in direct proportion to the intensity and duration of the exercise. Feeble hunger contractions may continue during moderate running. There appears to be some increase in the gastric tonus and hunger contractions as an after effect of moderate exercise. Stimulation of the cold nerve-endings of the skin does not affect the vagogastric tonus apparatus. If the stimulation is of sufficient intensity it induces (especially in man) a temporary inhibition of the gastric-hunger contractions via the splanchnic nerves. A similar inhibition is induced by strong stimulation of the cutaneous nerve-endings for warmth. There is a distinct increase in the gastric tonus and hunger contractions as an after effect of prolonged and intense stimulation of the cold nerve-endings of the skin.

The vagogastric tonus mechanism is not influenced by the condition of sleep, except in the way of augmentation, owing to the elimination of all inhibitory processes via the splanchnic nerves. The vagogastric tonus mechanism is not affected by intellectual processes or emotional states, except in so far as these cause inhibition of the gastric tonus and hunger contractions via the splanchnic nerves. It is clear, then, Carlson says, that in normal individuals (man, dog) the vagogastric tonus apparatus, at least so far as it concerns the empty stomach, is physiologically isolated from the exteroceptors and from many, if not all, central processes, while the splanchnic inhibitory apparatus is readily accessible to these processes. The biologic significance of this exceptional and unique isolation of the tonus apparatus of the hunger mechanism probably lies in the importance of the hunger mechanism being regulated on its positive side primarily by the state of nutrition; that is, through the blood, rather than by the fleeting changes in the nervous system.

5. Adrenal Deficiency and Sympathetic Nervous System.—Complete ligation of both adrenal glands of dogs at a single operation, Hoskins and Wheelon found, causes within four to six hours characteristic weakness of the skeletal muscles—including those of respiration. The weakness is shared to a marked degree by the cardiac muscle. At a time when cardiac weakness is strongly in evidence blood-pressure remains at or near its initial height. A compensatory activity of the vasomotor system therefore occurs. Vasomotor responses to faradic stimulation of the crural nerve persist. The vasomotor reactions to epinephrin also persist undiminished. The reactions to nicotin are often somewhat exaggerated as compared with preliminary observations with the same dosages. The vasomotor system, therefore, as well as the vascular musculature are unimpaired at a time when marked asthenia of skeletal and cardiac muscle has developed. This asthenia is sufficient alone to account for the final fatal results of adrenal extirpation. The authors found no evidence, therefore, that the sympathetic system suffers primarily in any degree from adrenal extirpation.

7. Cardiovascular and Temperature Variations in Women.—In the study reported by King, observations made on the pulse and temperature of women support the usually accepted theory of a rhythmic movement in the life processes; the highest point is reached three to four days before the menses, the lowest point about three days after their cessation. With one exception, blood-pressure records of the systolic, diastolic and pulse-pressures made on eleven women gave such irregular results that they cannot be regarded as supporting the wave theory. King's results, as far as they go, seem to indicate that there has been a tendency to overemphasize the inefficiency of women during the menstrual period.

8. Influence of Curare on Vasomotor Reflex Threshold.—The author's results may be summarized in the statements: 1. The thresholds for vasomotor reflexes are not, as a rule, markedly affected by curare. 2. The vasoconstrictor center shows signs of impairment of unity under the influence of the drug, causing it under certain circumstances to exhibit gradations of response not unusual in uncurarized animals.

10. Epinephrin and Coagulation Time of Blood.—Cannon and Gray found that epinephrin injected intravenously in small doses (0.001 mg. per kilo) and in larger doses subcutaneously, will shorten coagulation time to one-half or one-third the former duration. The prompt shortening of the process after small doses is changed after larger doses (about 0.03 mg. per kilo) to a lengthening and later a shortening, or to a lengthening alone. The effect of epinephrin on the clotting time is not associated with any corresponding effect on arterial pressure. If the blood is confined anterior to the diaphragm, or if the intestines and liver are removed, epinephrin in small doses does not cause rapid clotting. The addition of a small amount of epinephrin to drawn blood does not hasten clotting. Increase of dextrose in the blood to 0.3 or 0.4 per cent. does not cause the rapid clotting seen after epinephrin injection. The explanation is suggested that epinephrin accelerates the clotting process by stimulating the liver (and intestines?) to greater activity in discharging some factor or factors in coagulation.

11. Hastening Coagulation by Stimulating Splanchnic Nerves.—Stimulation of the splanchnic nerves, Cannon and Mendenhall found, results immediately, or after a brief delay, in shortening of the coagulation time of blood. The degree and the duration of the effect varies—clotting not uncommonly takes less than half the time it took before stimulation, and this period of rapid clotting may last from ten to thirty minutes. The stimulation usually produces less marked effects as it is repeated. If the adrenal is removed on one side, splanchnic stimulation on that side does not shorten the clotting time; whereas splanchnic stimulation on the other side is still effective. The faster clotting is therefore due to increased adrenal discharge. Since stimulation of nerves supplying the liver and intestines does not hasten clotting, and since increase of epinephrin has no effect in the absence of the liver and intestines, the shortened clotting after splanchnic stimulation is accounted for by the action of adrenal discharge on the liver (and intestines?). The variations in the effects in different animals can be accounted for by variations in the epinephrin content of the adrenal glands in confined animals.

12. Hastening Coagulation by Pain and Emotional Excitement.—Stimulation of afferent nerves (sciatic, crural), or major operations under light anesthesia, markedly shorten the coagulation time of blood. Emotional excitement is the occasion for very rapid clotting (sometimes in less than a half minute), which becomes slow (three to five minutes) when the splanchnic nerves are cut. Pain and strong emotions have been proved to evoke secretion of the adrenal glands; and epinephrin hastens clotting. Rapid coagulation may reasonably be considered, therefore, as another instance of adaptive reaction serviceable to the organism in the injury which may accompany pain or which may follow the struggle that fear or rage may occasion.

25 *Clinical Observations of Defective Conduction in Branches of Auriculoventricular Bundle. E. P. Carter, Cleveland.

18. **Influence of Adrenals on Diabetic Metabolism.**—The subcutaneous injection of epinephrin in a well-nourished dog twenty hours after the ingestion of a standard mixed diet sufficient for maintenance caused an increase of the respiratory quotient from 0.77 to 0.89. From the former quotient Lusk and Riche calculated that 16 per cent. of the heat production was at the expense of glucose, while from the latter it appears that 62 per cent. had that source. Before the injection of epinephrin, 0.8 gm. glucose was oxidized per hour, and after the injection 7.4 gm. per hour. The dog became muscularly active about half an hour after the administration of the drug.

The subcutaneous injection of epinephrin in a dog which had received 50 gm. of glucose resulted, in one experiment, in a respiratory quotient for a six-hour period of 0.98, and a combustion of glucose amounting to 7.7 gm. per hour, corresponding to 82 per cent. of the heat production of the period. On repetition of the experiment six days later, the respiratory quotient was found to be 0.99 during a period of five hours, and the oxidation of glucose amounted to 7.6 gm. hourly, being the equivalent of 85 per cent. of the total calories produced. The heat produced from the oxidation of 7.5 gm. of glucose is 28 calories, and the basal metabolisms of the dogs did not exceed 20 calories per hour. This is suggestive that epinephrin does not cause a diminution in the power of the organism to oxidize glucose.

The theory that epinephrin causes a production of sugar from fat, decreases the power of the organism to oxidize glucose through inhibition of pancreatic function, and stimulates the thyroid so that protein metabolism is increased, Lusk and Riche hold is untenable in any of its particulars.

19. **Blood-Serum of Cows Immunized against Tuberculosis.**—Baldwin's experiments relate to the properties of the serum of a cow repeatedly immunized against tuberculosis during a period of ten years. Six intravenous inoculations of living human cultures of tubercle bacilli, both of virulent and weak-virulent infectivity, besides numerous injections of all forms of tuberculin, were given to this cow. Specific agglutinin, precipitin, opsonin and complement-deviating antibody were demonstrated in varying degree in the serum, but never reached a high content. The presence of a bacteriolysin was not demonstrated; neither was a bacillicidal effect recognized either in the serum or leukocytes. Living human tubercle bacilli "sensitized" with the immune serum showed increased infective power in guinea-pigs and rabbits as compared with normal cow-serum. The increased infective power was manifested by earlier and more marked reactions or inflammation following inoculation, and a wider spread of the disease than in controls. This acceleration of infection was not manifest unless the cow had recently received injections of pulverized bacillus residue, but the immune-serum-agglutinin titer was not always greater than the normal cow-serum. To explain the apparent paradoxical action of the immune serum, it is suggested that the strongly agglutinated bacilli were protected from injury by the leukocytes of the inoculated animal by reason of the clumping. The bacilli were presumably phagocyted in large masses, but more difficult of digestion for that reason. It may also be suggested that the bacilli laden with antibody (opsonin) were more rapidly phagocyted and scattered, but owing to the resistant wax were not digested in sufficient numbers. A "sensitized" *living* tubercle-bacillus vaccine is not safe or practicable when prepared from immune bovine serums, considering the above-mentioned results.

20. **Study of Intestinal Obstruction.**—The results of their investigations of intestinal obstruction are summarized by the authors as follows: There are two factors at work in producing the symptoms and causing death in this condition. First, the loss of water from the tissues, due to the excessive drain into the bowel in response to the irritation set up by the retained secretions. This water may be replaced by subcutaneous injection of normal saline solution, and the symptoms caused are thus entirely controlled with a saving of life. Second, the entrance into the circulation of poisonous materials, which occurs only when the mucosa of the bowel is damaged. This damage results largely from the trauma inflicted by the overdistention acting on the circulation, but possibly also by the chemical action of the digestive ferments stagnated above the obstruction. Such a damage having resulted, there occurs a bacterial invasion into the bowel wall with a death of tissue cells (which is invariably demonstrable by microscopic examination), and in this process the poisonous substances are elaborated. The action of these poisons is apparently not influenced by the administration of saline subcutaneously. The absorption of a poison from any source whatsoever, so long as the mucosa remains intact, is not a factor. The development of a bacteriemia as a cause of death is excluded.

23. **Method for Obtaining Standard Wassermann Antigen**—Field uses the extract from guinea-pig hearts because a larger number can be used for each batch of antigen, so that the individual factor is reduced to the vanishing point.

24. **Action of Atropin on Eosinophil Cells of Blood.**—Herrick found that atropin in ordinary, non-toxic doses has no striking influence on the eosinophil cells of the guinea-pig's blood. Given in toxic doses resulting in loss in weight and other signs of disturbed nutrition, and particularly when such doses are repeated as often as every twelve hours, there is a diminution in the number of these cells, and the eosinophilia following interval injections of serum is diminished or absent. It is probable that this effect of atropin is not specific, but is the depression of a highly specialized function by the general effect on nutrition of large amounts of a strong poison.

25. **Defective Conduction in Branches of Auriculoventricular Bundle.**—Carter analyzed the reports of twenty-two cases. He found that in the presence of lesions involving the conductivity of the branches of the auriculoventricular bundle, a distinct and characteristic type of electrocardiogram is obtained. To the ventricular contractions on which these depend the term *aberrant* may be applied. This type of electrocardiogram is frequently associated with aortic valve disease; it is distinct from that of hypertrophy predominant in one ventricle.

Bundle-branch defects are usually accompanied by defects in the main trunk, suggesting that the junctional tissues as a whole have a special pathology. Carter claims that the evidence is too slight to admit of any definite conclusions as to the relation between lesions of the bundle branches and the occurrence of extrasystoles, and that the electrocardiographic pictures of aberrant beats are probably of considerable prognostic importance.

34 Report of Leukocytic Inclusion Bodies. L. W. Hill, Boston.
35 *Poor Health in Child: Some Developmental Influences and Their Importance to Adult. J. Bryant, Boston.

30. **Diagnosis of "Tuberculosis" in Children Justified.**—In the absence of advanced tuberculosis or a recent infection with some acute disease which might cause a negative reaction, Hawes claims that a diagnosis of tuberculosis is rarely justified unless there is a positive skin tuberculin reaction.

Constitutional signs and symptoms are usually present and require careful study and investigation. If such symptoms are absent, a definite diagnosis is unwise, although this should not interfere with placing the child under proper treatment. Signs referred to the chest and lungs are of interest and value, if present; if absent, their absence should not preclude a definite diagnosis. If present without constitutional disturbance, look out for chronic influenza and pneumococcus infections. Positive roentgenographic evidence is of value in conjunction with other evidence. Diagnoses based on the roentgenogram alone are apt to be wrong, and are unjust to the patient.

35. **Poor Health in Child.**—Adhesions, ptoses and other demonstrable physical defects, according to Bryant, are of very common occurrence at all ages in both sexes, but the frequency of these defects in the adult is not markedly greater than in the child. It is not improbable that such defects may stand in a causal relation to some at least of the disabilities of the child and the adult. An anomalous ligament of Treitz may be a factor in obstruction of the duodenum. A simple double measurement of the thorax is presented, which is likely to prove an aid in the recognition of certain intra-abdominal abnormalities. This measurement is in a variable degree an indicator of physical efficiency, and is useful after the age of 5 years. The treatment of developmental defects is primarily non-surgical, and if properly carried out in the child is preventive, in that it will result in creating an adult not only personally more efficient, but one who may entertain the hope of having physically more perfect children.

36 Auto-Infection Associated with Intestinal Canal. G. E. Armstrong, Montreal.
37 Acidosis. V. E. Henderson, Toronto.
38 *Mentally Defective. G. S. Mundie, Montreal.
39 *Destruction of Sebaceous Glands, Sweat Glands, Hair Follicles and Diseases Thereby Cured. A. H. Pirie, Montreal.

38. **Mentally Defective.**—Mental deficiency is a defect of the brain, not a disease. It cannot be cured, but the condition of the child can be improved to a greater or less degree by careful and suitable treatment and training. The greatest etiologic factor is heredity; other important factors are the condition of the mother during gestation, tuberculosis, alcoholism and injuries after birth. Mundie urges that all mental defectives should undergo a thorough medical examination, and any defect in vision, hearing or enlarged tonsils and adenoids corrected. Training should be carried out in institutions, and the teaching should be objective.

39. **Destruction of Sebaceous Glands.**—The following doses of Roentgen rays are prescribed by Pirie, for treatment of the conditions mentioned: Sycosis: 10 X one application to the diseased area. Acne vulgaris: 3 X to the diseased area on three consecutive days. Wait for three weeks and repeat. Continue this till six treatments have been given. Tinea tonsurans: 10 X to the whole scalp, one treatment only. Rodent ulcer: 10 X once a month till ulcer is healed, then once a month for six or twelve more treatments, or 30 X or 40 X for one treatment only. Hyperidrosis: 10 X once a month for four months. Then 8 X for two more treatments. Hypertrichosis: As for hyperidrosis. Cheloid: 3 X once a week for six to twelve months.

49 *External Bone Plating. H. R. Allen, Indianapolis.
50 Paratyphoid and Typhoid. W. Shimer, Indianapolis.
51 Colonic Alimentation. A. Graham, Indianapolis.

49. **External Bone Plating.**—Allen recommends an external plate poured and cast over the heads of nails whose shafts penetrate two hard layers of bone. This external cast is melted or the shafts of the nails cut as soon as bone union is established. The nails it is claimed are withdrawn as easily and as painlessly as removing sutures after an external wound heals. After several years' experience with projecting wires and nails, Allen has thus far not had a single case of infection. In removing or casting the external plate there is little danger of burning the patient, since the metal Allen uses is a low-melting alloy. It is composed of a combination of metals that take a hard tough temper if cooled suddenly, and becomes more or less brittle if cooled slowly.

Concerning the nails or pins or wires, Allen recommends long, thin, small-headed wire nails or brads and drills that make neat fitting holes. The nails should pass through two layers of hard bone, because this provides much more strength than can be secured by five or ten times as many screws that merely have 1/16 to 3/16 of an inch bearing in hard bone, while the greater proportion of the screw length is left projecting into soft bone-marrow or cancellous tissue. The nails, unlike the screws, should never be parallel. The nails may be made of any good strong metal or may be plated with nickel or silver or other metal. They may have round or polyhedral sides, with smooth or uneven shafts, with or without projections or bends. The ends may be alike or unalike, a head at one end and a point at the other, or terminating in bends or knobs, or eye-holes, or notches, or have castings on their end or ends.

An open incision is made for observing the fractured zone. Holes are drilled and nails put through the holes about 1 inch or more from the fractured zone. The bones are set accurately by hand under direct vision and digital contact; while accurately set, the cast is made. If the work is properly done the bones remain in accurate position. If the soft tissues bind against the shafts of the nails, cut the soft tissues and relieve the tension. Let the soft tissues fit loose about the projecting nails, because this means unqualified comfort after the patient comes out from the anesthesia. Allen always uses an auxiliary splint made out of wire and adhesive plaster.

66. **Studies in Anaphylaxis.**—The anaphylactic condition, Weil claims, is entirely dependent on the sensitization of the cells of the body. All conditions which in any way influence the degree of sensitiveness of the cells in the same degree alter the anaphylactic state, or sensitiveness, of the animal. The presence of immune bodies in the blood, whether in large or in small amounts, does not in the slightest degree contribute toward the production of the anaphylactic response in the guinea-pigs.

67. **Administration of Potassium Iodid.**—Smith found that the administration of potassium iodid to a guinea-pig in which a piece of its own thyroid gland has been transplanted does not seem to have any marked effect on the behavior of the graft. He did not find atrophy of the grafts, as reported by Cristiani, after the use of thyroid tablets. However, thyroid grafts show early central necrosis. The peripheral acini only remain intact. Regeneration takes place by the growth of thyroid tissue from the peripheral acini toward the center.

69. **Typhus Exanthematicus.**—The sera of patients infected with Typhus exanthematicus, Jablons claims, give the Wassermann complement-deviation test, as observed in syphilis, framboesia, leprosy, scarlet fever and malaria. This reaction, he says, need not be carried out with typhus organ extract; since the components that give the Wassermann syphilis test also give it here, and is therefore not specific for this disease. The absence of a positive Widal agglutination test in the presence of an epidemic he considers of value in making the diagnosis. The absence of positive bacteriologic findings and the presence of the Wassermann complement-deviation test point to the fact that the cause of the disease is to be sought for among the class of protozoan organisms.

71. **Experimental Study of Bile.**—When introduced into the stomach of the cat or the dog, Smith found that bile in the presence of an excess of 0.5 per cent. hydrochloric acid may cause injury to gastric mucous membrane, whereas bile 0.5 per cent. hydrochloric acid introduced alone into the stomach is without harmful effect. Lesions of the gastric mucous membrane produced by bile in the presence of an excess of 0.5 per cent. hydrochloric acid consist of necrosis of epithelium and interglandular tissue with hemorrhages into the mucous membrane, as a result of which small superficial ulcers may form. Ulceration of gastric mucous membrane, following the introduction of bile and hydrochloric acid into the stomach injected by way of the duodenum, is produced most readily between the third and the fifth hour after meals; least readily in the fasting stomach or shortly after the ingestion of food. If confined in the fasting stomach by ligating the esophagus and the duodenum, bile in the presence of an excess of 0.5 per cent. hydrochloric acid is more toxic for gastric epithelium than either bile alone or bile in the presence of an alkaline solution, such as 0.5 per cent. sodium carbonate. The presence of mucus in the stomach protects gastric epithelium against injury by bile and hydrochloric acid.

72. **Middle Coat of Radial Artery.**—MacCordick claims that the arterial musculature grows like other tissues, increasing both in the number and the size of the individual fibers. It appears to reach its optimum normal development between the ages of 20 and 30 years. While this is so, it retains its power of growth and proliferation throughout life, or certainly up to 76 years. It exhibits well-pronounced capacity to undergo both individual hypertrophy, that is, increase in size of the individual fibers, and numerical hyperplasia, that is, increase in the number of its constituent fibers. Of these, numerical hyperplasia is the more frequently encountered, and this particularly in cases of general arteriosclerosis and chronic nephritis. In the medical overgrowth of general arteriosclerosis, "zonal hyperplasia" is occasionally a marked feature—a numerical hyperplasia showing itself particularly in the inner zone of the media. In like manner the arterial musculature may exhibit both atrophy and numerical hypoplasia. These conditions may be either generalized or local. There are indications that the hypertrophied and hyperplastic media is liable to give place to a condition of atrophy.

73. **Neuroblastomata.**—Nerve tissue may give rise to new growths, which are properly called neuroblastomata. They may occur in any part of the nervous system, and Wahl says are of two types, according as they are composed chiefly of differentiated or undifferentiated elements. The neurocytoma is the undifferentiated type arising in the cerebrospinal nervous system. The corresponding type derived from the sympathetic system is the malignant neuroblastoma of the sympathetic nervous system or the "sympathoma embryonale." The ganglioneuroma and the chromaffin tumor represent the differentiated nerve growths, the latter taking its origin only in the sympathetic nervous system, the former arising also in the cerebrospinal nervous system. Most neuroblastomata, especially of the undifferentiated type, arise in the sympathetic nervous system.

77. **Calcium Therapy of Tuberculosis.**—In looking over the mass of literature on this subject, Kahn says one is left in doubt whether the use of lime in the treatment of tuberculosis is to be recommended. There is, however, no danger in its use, and according to the observations of a number of physicians, it is of marked benefit.

80. **Scarlatina Treated by Vaccines and Method of Milne.**—One hundred and twenty-eight scarlet-fever patients were treated by Schultze and Goldberger, with a vaccine prepared from the *Micrococcus "S"* (Schultze). In addition to the vaccine injection, all the patients received a preliminary course of eight or ten doses of calomel, 1/10 to 1/4 gm., and castor oil or citrate of magnesia, and also had their throats swabbed with a 10 per cent. solution of phenol in oil and their bodies rubbed with a 10 per cent. solution of eucalyptus in oil, as advocated by Milne. A few patients after having been subjected to Milne's treatment, passed smoky urine, an evidence of too great absorption of phenol. The authors temporarily discontinued the use of phenol and the urine promptly cleared. They then diminished the strength of the phenol solution to 5 per cent. and have been using the 5 per cent. strength ever since, with no untoward effects. Milne advises painting the tonsils with phenol solution every two hours for the first twenty-four hours, later diminishing the frequency according to the appearance of the throat.

The authors suggest painting the posterior pharyngeal wall, as well as the tonsils, and continue painting until cultures from the throat show no more "S" cocci. The rubbing in of the eucalyptus oil they found was very soothing, and in many cases relieved the intense itching, which accompanied desquamation. The phenol swabbing of the throats and the rubbing in of eucalyptus oil in the bodies were continued throughout the course of the disease, and in a few cases were also used as a prophylactic measure on some of the healthy members of the family with very good result. The vaccines used were three in number, composed of the following organisms: (1) *Micrococcus "S,"* 400 million per c.c.; (2) streptococcus, 400 million per c.c.; (3) *Micrococcus "S"* and streptococcus (combined), 400 million per c.c. In 103 of the cases only culture "S" vaccine was injected. The other twenty-five cases received the *Micrococcus "S"* and streptococcus vaccine (combined), but as the results obtained by the use of the combined vaccine did not seem to be any better than with the culture "S" vaccine alone, the use of the combined vaccine was discontinued. The dosage of each injection was estimated according to the age of the patient and the severity of the disease.

Of the 103 cases that were given only "S" vaccine, 55 received 1 c.c., 41 received 2 c.c., 5 received 3 c.c., and 2 received 4 c.c. Of the 25 cases that were given the combined vaccine, 10 received 1 c.c., 10 received 2 c.c., 2 received 3 c.c., 2 received 4 c.c. and 1 received 7 c.c. In 121 of the whole series of 128 cases, only one injection was found necessary. Of the other 7 cases, 3 cases received two injections, 2 cases received three injections and 2 cases received four injections. The necessity for reinjecting a patient was judged by the reaction obtained from previous injections.

In most of the cases the reaction was rather striking. The temperature fell by crisis, reaching normal in from twenty-four to seventy-two hours; the general condition of the patient improved markedly; whereas, before injection, many of these patients "looked sick," soon after the injection, however, their general mental and physical conditions showed such improvement that their facial expressions were those of well-being rather than of severe sickness; usually they felt hungry and cried for food, although in some cases the rectal temperature registered 104 or 105 degrees. Of the 128 cases, there were 2 deaths (1.5 per cent.). Seven were complicated with diphtheria. Complications were: adenitis, 7 (5.46 per cent.); nephritis, 7 (5.46 per cent.); otitis media, 3 (2.34 per cent.); arthritis, 3 (2.34 per cent.); pneumonia, 1 (0.86 per cent.); measles, 1 (0.86 per cent.); arthritis and endocarditis, 1 (0.86 per cent.); total, 20 (15.62 per cent.).

82. **Bacterial Vaccines in Scarlatina.**—The bacterial vaccines employed by Kiefer and Ferry were as follows: A vaccine composed of streptococci isolated from the nasopharynx of individuals suffering with typical symptoms of scarlatina; a vaccine composed of an organism isolated from the same situation, called *Micrococcus "S,"* and a vaccine composed of a mixture of the two. These vaccines which were polyvalent, being composed of several strains of each organism, contained 400 million organisms per c.c. each. Two lines of treatment were undertaken: prophylactic and curative, the nurses receiving the prophylactic treatment and the patients the curative. For curative purposes the three vaccines were used as described, while, for prophylactic purposes, the *Mic. "S"* vaccine alone was tested.

The patients treated were proportioned as follows: Those receiving the streptococcus vaccine, 29; the *Mic. "S"* vaccine, 44; and the combined vaccine, 33. The vaccines were given about every two or three days, starting with one-half a cubic centimeter and increasing the dose as the symptoms warranted; and the treatment, as a rule, was continued until the termination of the case. No set rules for the course of treatment were adhered to; this was left entirely to the judgment of the physician in charge. The vaccines which contained the streptococci had an advantage over the ones containing the *Mic. "S"* alone, as well as over the usual expectant treatment Whether the *Mic. "S"* bears any relation to the disease, it would appear from the study of these few cases that, as a curative agent, a vaccine composed of this organism alone would not be indicated. This is also partly borne out by the fact that the *Mic. "S"* is more easily isolated and is found in larger numbers in the early stages of the disease, and has not been isolated from any of the discharges. For prophylactic purposes the *Mic. "S"* vaccine was given in three doses of increasing strength with three- to five-day intervals between doses. The doses contained 200, 400 and 800 million bacteria, respectively. Up to the time of starting this work six nurses out of about 100 had contracted the disease. However, since the introduction of this vaccine as a prophylactic measure among all nurses who had not already had the disease, not a case has been reported. It is interesting and rather significant also that during a period of three months when the prophylactic treatments were discontinued, four out of about twenty nurses became infected.

1. **Cause and Cure of Cancer.**—From the laboratory point of view, Lazarus-Barlow tries to show how radiobiologic research indicates radium and other radiations as a very special agency wherewith to treat cancer; how certain disadvantages are unavoidable and others avoidable with our present knowledge; how, and in what directions, research should be conducted to turn present failure into future success. The ideal he holds is that in radium and other radiations we hold the solution of the cure of cancer. In a sufficient dose radium and other radiations are capable of killing every type of cell met with in cancer.

The action of radiations on cells, he claims, is selective, or conversely; all varieties of cells are not equally vulnerable to radiations. There is some evidence that an active immunity is produced as the result of acting on malignant cells with radium. Lazarus-Barlow insists that microscopic examination by a competent morbid histologist should be made of every case subjected to radium treatment. The amount of radium in use should be verified periodically by a competent physicist. It should be recognized that the metabolic processes of every patient after exposure to a considerable dose of radium are profoundly modified, at least for a time. Treatment with radium should not follow immediately on operation. If radium treatment of a malignant new growth be decided on, such treatment should not be preceded by complete removal of the main part of the growth.

Finally, Lazarus-Barlow states that, whatever treatment may be the case in the future, for the present radium treatment of malignant disease should be confined to those cases for which modern surgery cannot offer a fair prospect by operation. But this is the furthest that one can go. At present, where modern surgical operation can offer a fair prospect of satisfactory result, the knife must be recommended in preference to every other agent, and this is as true for recurrences as for the primary disease.

3. **Intramedullary Tumor of Spinal Cord.**—The case reported by Clarke and Lansdown was one of intramedullary tumor of the lumbosacral region of the cord, found irremovable at operation, some weeks later treated by placing a tube containing 50 mg. radium for twenty-two hours in the spinal canal, with the result of steady and progressive improvement in movement and sensation in the previously paralyzed lower limbs, until the onset of an acute cystitis with *B. coli* infection wore out the patient's strength and caused death.

4. **Roentgen Rays and Radium in Treatment of Cancer.**—In early cases, whether for preoperative or postoperative irradiation, the Roentgen ray is preferred by Hernaman-Johnson to the radium tube. When surgical removal is impossible, he says, a tube of radium should be buried in the center of the tumor, but Roentgen rays should be used, in addition to the surrounding area, and to any organs where a metastasis is likely to occur. This combined treatment may result in some actual necrosis in the immediate neighborhood of the radium, but so long as this is confined to the interior of the neoplasm, no harm will result. Finally, radium therapy is Hernaman-Johnson's method of choice in cancer of the vagina, uterus and rectum; but even here he states Roentgen rays form a useful adjunct, so far as adjacent parts are concerned.

21 *Pathogenicity and Virulence of Bacteria. F. H. Thiele and D. Embleton.
22 Sexual Disease and Individual. A. Corbett-Smith.

21. **Pathogenicity and Virulence of Bacteria.**—The authors consider that the toxicity of an organism hitherto supposed to possess an endotoxin or exotoxin really depends on the liberation of toxic proteoclastic degradation bodies from it by the ferments of the host. The pathogenicity of an organism depends on the relationship between the ferment activity and the amount of bacterial protoplasm, whereby toxic degradation bodies accumulate in sufficient quantities to cause symptoms. The virulence of an organism depends on the power that the organism has of exuding around itself a zone of its own protoplasm, in which the toxic degradation bodies liberated by the ferments can be maintained in position; to act, on the one hand, as an aggressive shield against the phagocyte, and a protection against the further action of the ferment on the other hand. The infectivity of an organism depends on (*a*) its virulence, and (*b*) the relative activity of the ferments of the host.

Journal of Tropical Medicine and Hygiene, London

May 1, XVII, No. 9, pp. 129-144

23 *Murmekiasmosis Amphilaphes. A. J. Chalmers and J. B. Christopherson.

23. **Murmekiasmosis Amphilaphes.**—The authors have observed a peculiar form of cutaneous wart characterized by an extraordinary facility for growth, causing it to spread and to occupy practically the whole of the right side of the face

and neck, involving the external auditory meatus, destroying the right eye and even invading the mucous membranes of the mouth, gums, tongue and throat. Microscopically, the points of interest about this curious warty mass are the presence of numerous cryptococci and the fact that the cutaneous warts are largely composed of an adenoma derived from sebaceous glands which feature is absent in those on the tongue. The disease is readily curable by operation. The most important clinical feature of the disease is the wart, and therefore the authors propose to name this apparently new human disease "*Murmekiasmosis Amphilaphes.*"

The leading diagnostic features are: (*a*) The presence of a warty growth, the individual members of which are painless, firm, do not readily bleed and do not readily ulcerate, but which tend to slowly spread and to endanger or destroy important organs. (*b*) The proliferation of the germinal layer of the sebaceous glands in the cutaneous warts (the authors can well imagine a condition in which the proliferation would produce a carcinomatous and not an adenomatous appearance), with the absence of this feature in the lingual warts. (*c*) The non-involvement of lymph-nodes, the non-formation of metastases and the non-malignancy of the growth. (*d*) The non-recurrence after removal. (*e*) The fact that the warts grow on healthy skin and not on cicatrices, and do not grow at first in any special relationship to mucous openings or moist areas of skin. The only effectual treatment is removal by means of a series of large dissecting operations, when the whole growth comes away like mats of warts, leaving large areas to be covered in by skin flaps and by skin grafting. Damaged organs, such as the eye, must be removed.

30 Case of Carcinoma of Breast in Male. H. V. Welch.
31 *Aspiratory Function of Heart. H. W. Verdon.

27. Hyperacute Streptococcal Infection.—The radical removal of tuberculous glands in the neck, while in Jefferson's opinion the only rational procedure, is not unfraught with danger. This is especially the case in the presence of a sinus. Two cases operated on by Jefferson died from a fulminating streptococcal infection, one twelve hours, and the other twenty hours after operation. The exact source of infection was not discovered, but Jefferson believes was probably from the walls of the sinuses present. He emphasizes that prophylactic treatment should be carried out for a few days before operation. The sinuses should be well swabbed out with iodin or similar antiseptic. The wound should be well washed out with saline before it is closed and drainage employed, preferably through a separate stab wound in the skin flap. In children at least probably no treatment will avail when once the bacteriemia is established.

29. Crucial Ligaments in Hemarthrus and Injuries to Knee.—Complete rupture of the internal lateral ligament of the knee, Corner says, is impossible without a complete rupture of the crucial ligaments. Partial rupture of the internal lateral ligament is produced by the crucial ligaments withstanding the strain of the accident and preventing complete rupture. The results of treatment will be *satisfactory. Complete or* severe lacerations of the internal lateral ligament will always be accompanied by a lesion of the crucial ligaments, even to the complete rupture of the anterior crucial ligament. The results of treatment vary *pari passu* with the extent of the laceration of the crucial ligaments. The convalescence may be long and the final result unsatisfactory.

31. Aspiratory Function of Heart.—The heart, Verdon says, is a pump and, like the mechanical pump, possesses aspiratory and propulsive powers—aspiratory power to draw supplies from pulmonary and systemic veins, and propulsive power to discharge the contents of its ventricles into pulmonary and systemic arteries. The heart works in a minus-pressure environment which at the height of inspiration registers 30 to 50 mm. Hg and during expiration falls to half this measure. Since fluids flow in the direction of the least resistance a centripetal current of blood from pulmonary and systemic sources sets in toward the minus-pressure environment of the heart, filling the great tributary veins, the auricles, and the ventricles. Intrathoracic minus-pressure thus constitutes a potential aspiratory force which keeps the central venous system perpetually full of blood, and maintains this section of the circulation under favorable conditions for the action of the kinetic aspiratory function of the ventricles.

The kinetic aspiratory function is intermittent and exercises itself only during systole. When the cone of the heart contracts and expels the contents of the ventricles into pulmonary and systemic arteries it vacates a section of the pericardial sac, a space which is instantly filled by the head of the venous column entering and expanding the auricles—the advance movement being rendered imperative by the *vis a tergo* of atmospheric pressure exercised on the contents of pulmonary and systemic veins lying at the foot of the venous column. The aspiratory function may be lowered by asthenic states of the myocardium or by reduction of the minus-pressure of the environment. When aspiratory function is lowered certain phenomena occur. Congestion of the pulmonary stream and stasis in bronchiolar radicles display themselves in symptomatic expression by asthma and dyspnea. The barrel chest of emphysema is the result of attempts made by inspiratory musculature to neutralize the untoward effects of minus-pressure insufficiency.

34 Kyphotic Pelvis and Cesarean Section. A. Herrgott.
35 The False Appendicitis of Pregnant Women. M. Vautrin.

33. Incomplete External Rupture of Body of Uterus.—Fraipont reports a fatal case of this rare complication. The placenta was normally located but had separated prematurely. Necropsy showed several superficial fissures in the peritoneal investment and in the subjacent muscular tissue; none was deep. The premature separation of the placenta favors these superficial fissures by the infiltration of blood into the uterine wall back of the placenta site. This renders the uterine tissues friable, and the possibility of fissuring on the outside should always be borne in mind when the placenta is prematurely cast off.

40 *Resection of the Knee for Osteosarcoma; Joint Implants. (Greffes semi-articulaires et résections typiques ou atypiques du genou pour osteo-sarcomas.) P. Mauclaire.

38. Snapping Hip-Joint.—Coudray calls the true snapping hip-joint that in which there is transient and intermittent subluxation of the head of the femur outside of the acetabulum. The false snapping hip-joint is that in which the cracking noise is not produced in the joint proper but on the greater trochanter. This latter type is the most common. He shows the mechanism of each by illustrations and states that it is liable to induce some disturbance and call for operative intervention. Various technics have been applied for the purpose and the outcome has been excellent. The anomaly may be congenital or acquired but the results of operative treatment seem to have been about equally good in each form, as he reviews the published experiences.

39. **Present Status of Operative Treatment of Pulmonary Tuberculosis.**—Lapeyre takes rather a discouraging view of "collapsotherapy," as artificial pneumothorax can be induced only in about 1 or 3 per cent. of all cases of pulmonary tuberculosis, and has cured the patient only in about 8 per cent. of the cases on record in which it has been applied. Plastic operations on the walls of the chest are too much of a strain on the patients weakened by their tuberculosis; the mortality has been high, and is far from counterbalanced by the results obtained. Resection of the diseased part of the lung, especially the apex, he regards as logical treatment, simple and not so much of a strain. Tuffier extols it and has reported one patient cured for seven years, Stretton one for six, and MacEwen one cured for eighteen years. This operation has been discarded, but Lapeyre thinks that recent progress in technic justifies taking it up again. Extrapleural pneumolysis, detaching the lung and filling in the space with fibroma tissue, omentum, Beck's paste or paraffin, has been applied by Tuffier in sixteen cases since 1910, and ten of the patients seem to be materially benefited, as also in Jessen's six cases.

40. **Resection of the Knee.**—Mauclaire states that the outcome has been very disappointing in his conservative operations on the knee for sarcoma in the bone, with the single exception of myeloplax osteosarcoma. This type of tumor does not seem to be malignant, and partial resection and scraping out the growth are safe as a rule. But with all other forms of sarcoma, round or spindle-celled, radical treatment should be urged. If refused or if the growth is of the myeloplax type, a modeling resection will generally give good results by the technic he describes, with illustrations, and compares with the literature on the subject. In one case reported he resected the epiphysis of the tibia and implanted the shaft of the tibia in the femur, giving a very good functional result.

43 Legislation on Rest after Childbirth. (La loi sur le repos des femmes en couches.) A. Levant.

42. **Blood-Dust in Diagnosis of Liver Disease.**—Jeannin and Levant recall that the hemokoniae in the blood, the small refractive bodies seen in a drop of fresh blood, increase in large numbers after ingestion of butter when the liver is sound. It is thus a simple matter to examine the blood for these bodies, and if they are found in scanty numbers this may be regarded as a sign that the liver is functioning defectively. They report two cases in which they applied this alimentary lipemia test to women with severe jaundice after a childbirth. There were scarcely any hemokoniae to be discovered in the blood in the first case and the grave prognosis from this was confirmed by death the seventh day after delivery. There were no hemorrhages nor nervous phenomena, but the jaundice was extremely severe and the liver was found much degenerated, with streptococci in some of the lobules. The symptoms were not severe enough at first to suggest a fatal outcome but the absence of blood-dust in the fresh blood compelled the gravest prognosis. In the second case the jaundice was mild and there were no threatening nervous or hemorrhagic disturbances. The woman had been in labor for three days with breech presentation, temperature 38 C., pulse 120. Here too only 15 or 20 hemokoniae were found in the drop of blood, and she died the sixtieth hour after extraction of the dead fetus.

In three other cases the women presented jaundice in the course of pregnancy; one had very severe catarrhal jaundice with clay-colored stools and seemed to be in a bad way, but the hemokoniae were found in normal numbers. The woman recovered and the pregnancy proceeded normally to term. In two other cases there was subjaundice; the women did not vomit much, the diacetic odor of the breath was not at all pronounced, but the small number of hemokoniae in the blood gave the warning that the women were on the way to pernicious jaundice, and prompt interruption of the pregnancy seemed their only salvation. The test is made by examining the blood fasting and then again after the woman has eaten 50 gm. of butter on bread. Three and a half hours later the hemokoniae show up in large numbers under normal conditions, every slide in the microscope looking like a "milky way" and alive with movements of the refractive particles from the alimentary lipemia.

44 *Diagnosis of Gastric Cancer by Cells Found in Rinsing-Water. (Le cytodiagnostic de l'estomac.) Loeper and E. Binet.
45 Uncontrollable Vomiting of Pregnancy, Sometimes Amenable to Impressive Psychotherapy. (Toxémie ou névrose?) J. Beloux.

44. **Diagnosis of Gastric Cancer by Cells Found in Rinsing-Water.**—The technic which Loeper and Binet have found so useful has already been described in these columns (May 16, p. 1587). They here review their experiences with it to date which confirm the importance of the findings with the test when applied to the fasting stomach and so cautiously that the lining of the stomach suffers no injury. It has demonstrated that purely functional stomach derangement is extremely rare, while unsuspected gastritis is astonishingly frequent, especially the superficial and transient forms with more or less congestion, desquamation and diapedesis. The cytodiagnosis reveals that a tendency to ulcer is at the bottom of many cases of supposed simple dyspepsia, and it warns when the ulcer is becoming malignant, revealing the onset of the cancer long before it can be detected in any other way. The article is accompanied by twenty-one illustrations of the types of microscopic findings found with various stomach affections, mild and malignant.

51 *Tardy Ulnar Paralysis after Fracture of External Condyle of the Humerus. A Mouchet.

50. **Amputation of Cervix for Prolapse.**—Ten illustrations show the various steps of this method of treating genital prolapse by supravaginal amputation of the cervix plus colpectomy involving mostly the anterior vaginal wall, and posterior colpoperineorrhaphy. This removes the hypertrophied cervix and entails more or less atrophy of the rest of the uterus while it reduces the size of the lumen and the length of the vagina and supplies a solid support for the uterus and bladder.

51. **Tardy Ulnar Paralysis.**—Mouchet reports with illustrations four cases in which after fracture of the external condyle of the humerus, ulnar paralysis developed later after an interval of several years up to thirty. The fracture generally occurred in childhood. The result in time is a valgus deformity and this in turn stretches and induces inflammation of the ulnar nerve, and the neuritis gradually entails paralysis. Operative correction of the valgus deformity relieves the strain on the nerve and puts an end to the paralysis. A wedge-shaped resection of the humerus above the condyle, the broad end of the wedge toward the body, corrects the valgus deformity.

57 *Reflux of Urine by the Ureter after Nephrectomy. M. Lévy-Weissmann.
58 Test Polyuria. (Contribution clinique à l'étude de la polyurie expérimentale.) E. Pirondini.

53. **Ultimate Outcome of Plastic Operations on the Urethra.**—Josserand has traced to date twenty-one patients on whom he had operated for hypospadias or epispadias several years ago. Only three were adults. The new urethra formed from the skin-epidermis flap in a tunnel hollowed out for it has stood the test of time, six, seven and twelve years having elapsed since in several of the cases. Two of the patients have had gonorrhea. He first closes the natural orifice and diverts the urine through an opening in the perineum into the urethra. The formation of the new urethra is the next step; internal urethrotomy later ensures a normal-sized lumen and then the perineal fistula is closed up. By operating thus in stages there is only exceptionally a tendency to a fistula. In three cases the artificial urethra grew wider as the boys grew generally. In one case there was a transient stricture which yielded to a few attempts at dilatation. A permanent stricture developed further in three cases in which the field of operation became infected; the infection was traced to a thread left in the new urethra to facilitate catheterization or to a retention catheter introduced into the bladder through the perineal opening. These procedures opened the door to infection which entailed slight stenosis requiring occasional dilatation to keep it under control.

57. **Reflux of Urine through Ureter after Nephrectomy.**—Weissmann says that he has been able to find only fifteen cases on record of this reflux of part or all of urine from the sound kidney. He reports a case from his own service, the urine from the bladder pouring out of the ureter stump where it had been brought out through the lumbar incision left from the nephrectomy. The flow continued uninfluenced by changes of position until finally the incision healed and the urine was voided by the natural route. The wound opened again a week later during hard coughing and part of the urine poured through it anew. The cause of the reflux is probably the irritable condition of the bladder in consequence of the tuberculous process for which the kidney was removed. The bladder contractions are so vigorous that the sphincter closes with them, and the urine is forced up into the empty ureter. The walls of the ureter, besides, have had their elasticity impaired and are unable to oppose the physiologic resistance to the reflux. It may keep up for several days or weeks, six months (Rafin), seven months or a year (Desnos). In Hartmann's case a secondary ureterectomy became necessary, but in all the others a spontaneous cure was finally realized.

Lyon Médical

April 26, XLVI, No. 17, pp. 913-968

59 *Ramifying Bone Growth in the Lungs. (Cas d'arborisation osseuse du poumon.) L. Mangini.

59. **Ossifying Sclerosis of the Lungs.**—Mangini has found records in the literature of twenty-three cases of an ossifying process ramifying in the lungs, and after searching for three years in his own necropsy work he encountered a typical example. The cadaver was that of a man of 62, and the bone needles could be felt in the lungs reaching down to the pleura, as many as ten or fifteen in each lower lobe, and cohering to form an actual arborization. The microscopic findings explain it as the ossification of fibrous nodules, the cicatrix of repeated inflammatory processes. Some of the branches of bone were 3 or 4 cm. long, and enclosed in a fibrous sheath. There was nothing to suggest tuberculosis, but for twenty-seven years the man had suffered from "colds" and cough each winter, and during the last six months the sputum had been blood-stained. There was no valvular disease but signs of incipient tabes.

62 *Curability of Uterine Cancer. J. L. Faure.
63 Symptoms from Steeple-Skull Deformity. (Le syndrome oxycéphalique ou syndrome de cranio-synostose pathologique.) M. Bertolotti.

62. **Uterine Cancer.**—Faure remarks that the results of operative treatment of uterine cancer have far surpassed the most sanguine anticipations of even a few years ago. Most of his patients operated on from eight to sixteen years ago are in good health to-day and we can count on at least 40 per cent. of permanent cures; in his private practice fully 70 per cent. are apparently permanently cured. As long as the uterus is movable he urges surgical intervention regardless of the extent of the lesion.

66 Radiotherapy of Uterine Fibroma. R. Gauducheau.
67 Pregnancy Cholecystitis. M. Audebert.

64. **Suture of Levator Ani as Cause of Dystocia.**—Pouliot's case is another warning against plastic operations for laceration of the perineum. The woman was at term with her second child, two years after an operation with myorrhaphy done six months after obstetric laceration of the perineum. The child's head was held back by a cord-like commissure of the vagina. Part of the perineum subjected to this strain developed gangrene but this was soon under control and recovery followed. Plastic operations on the perineum, with suture of muscles in this region, should never be done so as to interfere with child-bearing later.

76 *Is Tuberculosis of the Lymph-Nodes in the Pancreas Region of Air-Borne Origin? H. Gross.

69. **The Thymus in Exophthalmic Goiter.**—Hart says that his report of a case in 1908 was the first to call attention to the thymus as a factor in exophthalmic goiter. In his case a man of 29 with a typical case of this disease died suddenly and the thyroid was found apparently normal in every respect. The thymus, on the other hand, was abnormally large and scraps implanted in guinea-pigs proved extremely toxic; the controls bore without harm implants of thymus of other origin. Hart thinks it is now established beyond question that exophthalmic goiter can develop from an exclusively thyroid origin, from an exclusively thymus origin, and from a mixture of both. The predominance of the thymus factor seems particularly deleterious, and the more so, the greater the tendency to constitutional hypoplasia. The earlier the disease develops the greater the preponderance of the constitutional element. The defective development of the chromaffine system, especially the medulla of the adrenals, is one of the chief signs of the constitutional hypoplasia, particularly from the functional standpoint.

Many cases of Addison's disease, he adds, develop on the basis of defective development of the adrenals—a manifestation of constitutional hypoplasia. He found extreme hypoplasia of the chromaffine system in a number of persons who had died during or soon after operative treatment of exophthalmic goiter. In one such case exophthalmic goiter and Addison's disease had both developed on the basis of physical inferiority. Neither disease was secondary to the other. In another case there was slight bronzing and merely hints of exophthalmic goiter, but the defective functioning of the chromaffine system had entailed death without the typical symptoms having had a chance to develop. In other cases the chromaffine system was in actual hyperplasia, showing the excessive functional demands on it; we must not forget that a hyperplastic organ is liable to be functioning abnormally as well as a hypoplastic one. In operative treatment of exophthalmic goiter, the thymus should be attacked first, he says. After its partial or total removal, follow with resection of the thyroid.

70. **Intestinal Cystoid Pneumatosis.**—Demmer gives an illustrated description of what he thinks is the fifteenth case on record of this affection in man. His patient was a farmer of 42, and, as in nearly all the other cases, the cystoid pneumatosis followed old chronic gastro-intestinal trouble of some sort, generally gastric ulcer. In nine cases an operation was done for dilatation of the stomach and pyloric disease was found in five. In two cases a tuberculous process was found in the intestines. The total cases compiled are tabulated for comparison . The stretch of intestine involved in the cystoid affection was successfully resected in four cases, and was excluded from the rest of the bowel tract in two cases. In the personal case reported, it was found necessary to apply gastro-enterostomy on account of an ulcer at the pylorus; the appendix and a long stretch of the ileum were resected. That cystoid pneumatosis may retrogress spontaneously is demonstrated by Urban's case in which all the symptoms gradually and completely subsided after an exploratory laparotomy. Operative intervention is not necessary as long as there is no trouble from adhesions or obstruction of the gut. The symptoms in the case reported had been those of a recurring stomach trouble for six years. Then constipation of the severest type developed, the bowel moving only under strong laxatives or high enemas. The stool was like goat droppings at times, and black. He had been unable to go to work for nine months and been confined to bed for three, when the operation put him on his feet again, a clinically well man. There was a history of a contusion ten years before in the stomach region, but no venereal disease.

73. **Traumatic Subdural Hemorrhage with Long Interval.**—Vischer's two cases warn that after an accident liable to entail subdural hemorrhage the patient should be kept under supervision longer than is usually considered necessary. Signs of pressure on the brain did not develop until one or two months after the trauma, accompanied in one case by a brief attack of aphasia which permitted exact localization of the hematoma. An abscess was improbable on account of the normal temperature. No information was obtained from roentgenoscopy. Fresh and old blood and clots were found in the hematomas. The aphasia patient was entirely cured by the operation and the other patient's symptoms have subsided except a tendency to muscular paresis in one leg. This is probably the result of some slight subcortical injury of the brain at the time of the trauma and has nothing to do with the subdural hematoma. The headaches of which persons complain after an accident to the skull may be due to relics of submeningeal hemorrhage which at the time are not causing trouble otherwise. Trephining relieves not only *in these tardy hematoma cases* but also *in actual hemorrhagic pachymeningitis.* De Quervain operated successfully for this cause, relieving the brain from pressure by the blood, first on one side and later on the other, in a case of internal hemorrhagic pachymeningitis in a hard drinker.

75. **Direct Sunlight in Treatment of Tuberculous Fistulas.**—This long article is by an assistant at Rollier's sanatoriums in Switzerland and an assistant at Bier's surgical clinic at Berlin. Sixteen severe cases are reported in detail as typical specimens of what can be accomplished by months of sunlight treatment in old fistulous processes. Rollier reported last year a complete cure in 248 out of 331 cases of open tuberculosis. In the 16 cases reported the 4 in which the soft parts alone were involved have healed entirely, as also 8 of the bone cases but in 4 there is still a minute active process in the depths so that the fistula still persists although materially reduced in size. Fistulas in soft parts heal in four or seven months, but when a bone or joint process is the cause of the fistula a year is usually necessary, sometimes less, but oftener still longer. Kisch and Grätz say that even under a brief course of heliotherapy the fistulas show a marked reaction, including those that have previously resisted all conservative and surgical measures. The sunlight does not cause encapsulation of the fungous masses, but a breaking down of the disease tissue and its substitution by cicatricial tissue.

76. **Tuberculous Lymph-Nodes in Pancreas Region.**—Gross states that in the last two years he has encountered five cases of tuberculosis restricted exclusively to the lymph-nodes in the pancreas region. In the first case the tuberculous lymph-nodes, lying back of the common bile-duct, had compressed it and the gall-bladder. This woman of 65 for thirty-seven years had been subject to gall-stone colics, and the gall-bladder was finally removed. About ten months later symptoms developed anew, ascribed to a stone in the bile-duct. The duct was found empty, but compressed by the large swollen lymph-nodes, the seat of nodular tuberculosis with giant cells. Similar findings were also encountered at the necropsy of a young woman who had died from cholangitis after suffering two years from a stone in the common bile-duct. No tuberculous foci could be discovered except a single plum-sized, cheesy lymph-node back of the common bile duct. The third case was in a workingman who had had stomach trouble for years finally compelling operative treatment for the supposed gastric ulcer. The stomach was found adherent in the pylorus region and this was explained by a large tuberculous lymph-node close to the edge of the pancreas, surrounded by edema which spread toward and involved the pylorus. The big tuberculous node was excised and gastro-enterostomy done and the patient cured at one stroke. Exacerbations of the tuberculous process explain the course in these cases and throw light retrospectively on many puzzling cases of trouble in the upper abdomen. In another case colics in the upper abdomen and lately pain radiating to the back were the only symptoms presented by the young woman. An operation failed to reveal the expected gall-stones but showed tuberculous nodules on the mesocolon and extensive adhesions which were broken up. The patient has been in good clinical health since. The lymph-nodes involved in the five cases were all on the right side of the pancreatic lymph-node system, some in the upper and some in the lower part.

83 *Colored Plates to Show Proteolytic Action of Ferments and Antiferments. L. Brieger and Schwalm.

77. Size of the Heart at Rest and at Work.—Nicolai and Zuntz report experiments at the Athletics Research Institute at Charlottenburg which demonstrate, they state, that the heart increases in size during vigorous exercise and afterward is smaller than it was before the exercise was commenced. They examined persons working on a kind of treadmill, the chest fitted with a fluorescent screen so that the changes in the heart outline could be supervised. It seems almost certain that the heart normally contains always some reserve blood, to be called on in special emergencies. This explains why the diameter is larger when the heart is working quietly than when it has been pumped entirely empty in the course of vigorous muscular exercise.

80. Idiopathic Intercostal Neuralgia.—Tobias says that analysis of the cases of supposed idiopathic intercostal neuralgia almost always reveals some unsuspected cause which excludes them from the idiopathic category. He found only five cases that stood the test among the 1,400 patients at the Berlin policlinic for nervous affections since 1900. Of these five, herpes zoster on the left side was evident in three; another was a pronounced neurasthenic with left intercostal neuralgia. The fifth patient was a man of 39 with a history of gonorrhea; for eight weeks he had been suffering from unbearable left intercostal neuralgia which had come on suddenly. The knee-jerk and Achilles reflex were lost on both sides and the Wassermann test elicited a positive reaction. Thus the policlinic did not have a single case of actual idiopathic intercostal neuralgia during that period, and in Tobias' private practice he encountered only six cases which could not be traced to herpes zoster or cured by treatment for rheumatism. In three cases the discovery of an aneurism explained the "neuralgia" and in two others chronic inflammation in the vertebrae proved to be the cause of the bilateral intercostal neuralgia.

83. Improved Technic for Estimation of Ferment Action.—The proteolytic power of a fluid is instructively shown by the depressions eaten into a Löffler plate, and Brieger called attention long ago to the dimpling (*Dellenbildung*) in the Löffler plate as a simple and reliable test for antitrypsin in the blood-serum. It is here announced that the test is materially simplified by staining the mixture used for the plate. The depressions not only show up very much clearer but the proteolytic fluid decolors the mixture. A safranin stain, known as iris-violet, has been found most useful. Five drops of a 16 per cent. solution of the stain are added to the mixture which is made up of 80 c.c. fresh beef serum and 20 c.c. of a 2 per cent. solution of grape-sugar bouillon. A loop of the serum to be tested is mixed in turn with 1, 2, 3, 4 or more loops of the standard solution of trypsin. One drop from each of the mixtures is then deposited on the plate. If no dimples are hollowed out and there is no discoloration except with the 1 : 4 mixture, then the antitryptic power of the serum under examination is recorded as 4. This figure represents the normal standard.

Correspondenz-Blatt für Schweizer Aerzte, Basel

April 25, XLIV, No. 17, pp. 513-544

84 *Recent Progress in Diagnosis and Treatment of Pulmonary Tuberculosis. M. Landolt.

84. Recent Experiences with Pulmonary Tuberculosis.—Landolt reviews what has been accomplished in recent years at the Aarau Sanatorium, saying that tuberculin has rendered good service as an aid in differentiation, especially the reaction in the focus in the lung after subcutaneous injection. *He insists that this focal reaction must be scrupulously* avoided when tuberculin is being given for therapeutic purposes. The diazo reaction is unfavorable, especially if it keeps up. It is frequently positive with intestinal tuberculosis, and it is often negative in threatening pulmonary tuberculosis. In this latter case Weiss' urochromogen reaction may prove positive. He found the diazo positive in 43 and the chromogen in 204 of 395 patients tested, the latter test proving far more delicate. He often obtained a positive response with the latter and later, as the disease progressed, the diazo became positive. In the cases with a favorable course, the diazo dropped off first and later the chromogen reaction.

He found inunctions of a 10 per cent. guaiacol-petrolatum effectual in reducing the temperature; a small lump was rubbed into the skin twice a day. Artificial pneumothorax has been systematically induced in suitable cases but the precaution is always taken to inject oxygen at the first sitting, instead of the nitrogen which is used exclusively later. A brief syncope was observed in one case as the patient started to get up after injection of 400 c.c. of nitrogen; the pulse stopped entirely but tranquil breathing kept up; in two minutes she had recovered; she was subject to syncopes. This was the only occurrence of the kind in the 520 punctures for the purpose in the forty-eight patients given this treatment. They formed 33 per cent. of the 139 patients in the third stage of the disease, and many of them were materially benefited. Transient benefit was realized even in some acute cases, but the progress of the disease could not be permanently arrested. There was no air embolism in any case but mediastinal emphysema was observed in some and a pleural effusion was observed in 30 per cent. This is a very unwelcome complication as it may cause discomfort and production of adhesions later.

On the whole the immediate results of the pneumothorax were excellent in 65 per cent. of the cases, so that this method of treatment, he says, may be regarded as great progress. He does not approve of it in the milder cases; they may recover without it, and the procedure is more or less annoying and cannot be regarded as entirely harmless. But it is a welcome aid, and to sanatorium physicians in particular.

92. **Threatening Hemorrhage during Pregnancy.**—Jung remarks that tamponing is seldom necessary for hemorrhage from an abortion; but if the atony is such as to require it, the uterus must be packed to the fundus. The first thing, he emphasizes, when called to a case of hemorrhage from abortion is to take the woman's temperature, even before making any examination. Fever may be already installed when the physician first arrives, and if this is not ascertained at the time, he may be held responsible for the fever as the case progresses. He advises against the curet, whether the cervix is open or not, for fear of perforation, but as long as any relics of the abortion are left in the uterus and they are *keeping up hemorrhage, they must* be scraped out with the finger even if the case is already septic. It is a question whether to dilate the cervix with laminaria or a metal dilator; if there is already fever he prefers the latter.

The hyperemia of pregnancy is liable to start coexistent tumors to bleeding, and varices in the genitals or on the limbs may cause fatal hemorrhage. Tumors may be excised without interfering with the pregnancy if the uterus is spared as much as possible and the region is not tamponed afterward. If a varix in the labium or clitoris region bursts, manual compression is all that is possible, applying pressure with a cotton pad dipped in a weak disinfectant solution. The bleeding vessel is so friable that it does little good to ligate it, as a rule, and the only way to arrest the hemorrhage is to throw a stout ligature around the whole bundle of veins, applying a compressing T-bandage. With varices in the vagina the effort should be made to throw a ligature around the veins, avoiding the use of a tampon, to refrain from bringing on labor.

94. **Lipoids Indispensable in Food.**—Stepp found that his mice invariably died when fed on food from which the substances soluble in alcohol and ether had been removed. Restoring the alcohol-ether extract to the food rendered the food wholesome again for the mice. Addition of fat did not answer the purpose. His experiments point anew to the lipoids as representing the vitamins.

95. **Simplified Radiotherapy of Lupus.**—Jesionek presents arguments to show that the benefit from Finsen treatment of lupus is due to the inflammation-inducing properties of the rays and not to any direct bactericidal action from them. It is not necessary, he adds, to use such complicated technic to induce inflammation; the sun alone is able to inflame the skin. All the effect is not felt at the moment, but in twelve hours the skin shows signs of pronounced inflammation after prolonged exposure to the sun or, on cloudy days, to the mercury quartz lamp. At the dermatologic clinic at Giessen, this method of treatment has been systematically applied and with most excellent results. The therapeutic effect may be explained by assuming that the serum attracted into the patches of lupus by the inflammation brings a complement which enables the *amboceptors present* in the tuberculous foci to display their antibody action.

96. **The Friedmann Remedy.**—Friedmann reiterates that the turtle bacillus culture has always proved in his experience totally harmless for the guinea-pig. The infiltrations and nodules which occasionally develop at the point of injection are of a harmless and transient nature. They represent an intermediate stage and regularly retrogress, and further inoculation of guinea-pigs from them has never induced in any instance tuberculosis, that is, a progressive affection.

Rabinowitsch replies in detail to Friedmann's statements recapitulating what she said in a previous communication in regard to his remedy for tuberculosis (summarized in the Berlin Letter, page 1343), and adding further evidence to reenforce her protest against preventive inoculation of children. She states that the abscesses at the point of *injection* are not such harmless matters as Friedmann claims; she knows of a large number of Friedmann's patients who have had to suffer for months from these abscesses, in addition to the case she previously mentioned. She describes another in detail in which the woman lost 18 pounds in three months. She also calls attention to the necessity for discriminating between the "culture" and the "finished remedy." What Ehrlich said of the culture was *only from the bacteriologic* point of view and applied only to the harmlessness of the culture for animals. She says that it is certainly strange that Friedmann in his "long years of research" has never succeeded in inducing tuberculosis in guinea-pigs with his bacilli while others have obtained positive results in a few months. This testifies either that the culture is not a standard unit culture—as Friedmann claims—or else that the avirulent bacilli have acquired virulence in the course of time.

97. **Reaction of the Heart to Epinephrin.**—Roth states that in fifteen patients with heart disease and an equal number free from cardiac taint, injection of epinephrin caused a modification in the heart action to the extent of extra systoles when the heart was already pathologic, but not with the sound hearts. He discusses the nervous factors evidently at work.

98. **Galactosuria and Levulosuria in Tests of Liver Functioning.**—Wörner and Reiss declare that when 40 *gm.* of galactose are given for the test, an elimination of 3 *gm.* and more must be regarded as positively pathologic. Levulose given for this purpose must be in the dose of 100 gm., and more than 0.7 gm. must be eliminated before we can speak of a pathologic output. Alimentary levulosuria testifies in a general way to some injury of the liver. Pathologic alimentary galactosuria on the other hand, testifies to the existence of certain definite liver affections and thus permits differential diagnosis of catarrhal jaundice, phosphorus poisoning and fatty liver. Circumscribed liver affections, gall-stones and cancer do *not lower the tolerance for galactose unless* infection is installed.

111 Permanent Cures of Mammary Cancer. H. Lindenberg.
112 *Transplantation of Entire Knee-Joint. C. Deutschländer.

102. **Splanchnoptosis.**—Wiedhopf presents evidence to prove that the viscera sag because there is disproportion between the size of the abdominal cavity and the size of its contents. Treatment can aim to reduce the size of the cavity or to increase the bulk of the contents or both. The latter can be accomplished by eating more, while the size of the cavity can be reduced by toning up the abdominal muscles or wearing a bandage or by an operation on the abdominal wall or floor of the pelvis. He emphasizes that any "pexy" operation, fastening any organ to support it, is illogical in the extreme as it does not act on the cause. He has worked out a technic to correct splanchnoptosis which he thinks has everything to commend it as it reduces the size of the anterior abdominal wall and materially strengthens it without opening into the peritoneum. The rear aponeuroses of the rectus muscles are brought forward and the folds in each are sutured together.

104. **Outcome of Fracture of the Leg.**—Chiari has found that the ultimate functional outcome of a broken leg is better in those who were compelled to go to work early than in those who were paid a sickness indemnity and thus were able to spare their leg longer. The most favorable results were encountered on the whole in those whose stay in the hospital (Innsbruck) was relatively brief. This does not apply naturally to fracture of the malleolus, which must be

considered apart; his eleven bilateral cases of this class warn that plaster casts should be discarded in favor of extension or Lexer's bandage.

106. **Acute Pancreatitis**—In the twelve cases described by Rollmann the patients were nearly all corpulent and passing or past middle age. Gall-stone trouble was a factor in two, gross error in diet and abuse of alcohol in one. In one case the head was swollen and a *few foci of necrosis were all that was found at the gall-stone operation.* In two other cases the pancreas disease caused death from toxins in less time than usual with peritonitis from perforation. When there is much suppuration the course is generally milder. Several of the patients said they had had similar attacks on previous occasions, and the calcified foci of necrosis found in the mesentery in some cadavers testify that acute pancreatitis may sometimes heal spontaneously. Five of his twelve patients died; one developed diabetes five years afterward, and one still seems unable to digest fat properly.

112. **Implanted Knee.**—Deutschländer implanted an entire knee-joint after resection of the knee of a boy of 12 for deformity left from poliomyelitis. The results were not all that had been *anticipated, but were far from a total failure.* Most of the implant was in time destroyed and only a small fraction actually healed in place. The parts that were thus retained were all cartilage. By restricting the implant to cartilage alone we are thus more certain of final success, and the operation becomes much simpler, making less demands on the organism. It is in fact merely a form of the interposition technic.

126 *Differentiation of Diseases by Serodiagnosis. (Klinische Ergebnisse mit dem Abderhaldenschen Dialysierverfahren.) B. Forster.

120. **Scoliosis.**—Schanz declares that there is scarcely a case of curvature of the spine for which medical advice is not sought early in the case. The mother usually notices the deformity at once and hurries the child to the doctor. And the child's fate is decided chiefly by what the doctor says at this time. If the child is told to "stand up straight," the diagnosis and supervision of the course of the case are rendered practically impossible thereafter. Never tell a child under these conditions to stand up straight. The next thing, Schanz continues, is to determine whether the curvature is benign or malignant, and the course of the case is the only means to ascertain this. The malignant form develops considerable deformity in a few weeks or months; the onset before or after school life is also suspicious; likewise a history of trauma. The malignant form also grows worse at intervals, with periods of remission, but the course is progressive on the whole. He has had about one malignant case to ten benign ones; the latter do not require treatment as a rule. The mother can massage the back, the child can wear a brace or sleep in a plaster bed—this is generally ample. Too much gymnasium work is liable to transform a mild into the malignant type, and aggravate a malignant case. It is not necessary to take the child out of school; *resting the elbows on the school desk helps to relieve the spine. The scoliosis seldom grows much worse* during school life, but severe deformity may develop rapidly after leaving school.

121 **Alimentary Galactosuria.**—Maliwa tabulates the findings in twelve cases of liver disease, in ten of orthostatic albuminuria, and twenty-one other patients, after ingestion of 40 gm galactose, fasting. The data demonstrate that intolerance for galactose is by no means an unequivocal symptom of insufficiency of the liver. The kidneys often have something to do with it. When the latter is the case, the galactose elimination begins abruptly and in large amounts, dropping off equally abruptly. With insufficiency of the liver, the curve of elimination is generally more protracted.

125 **The Duodenal Tube.**—Gang and Klein expatiate on the important information to be derived from the use of the duodenal tube in various stomach and duodenum affections and in making tests of the digestive ferments, etc. They tabulate the details in twenty-one cases of intestinal derangements and in ten gastric ulcer or chlorosis cases.

126 **Serodiagnosis in Differentiation.**—Forster applied Abderhalden's ninhydrin technic to detect cases of incipient exophthalmic *goiter and states that treatment instituted on* the basis of the ninhydrin reaction gave constantly corroborative results. Among the cases related is that of a very effeminate man of 43 who for some time had complained of disturbances resembling those of women at the menopause. His serum digested ovary tissue but not testicle, thymus or thyroid tissue. The man is evidently a pseudohermaphrodite and this case suggests that the ninhydrin test may be found especially useful in puzzling cases of hermaphroditism, eunuchoidism, etc.

141 *Full Utilization of Vacations for Young and Old. (Ferienausnützung für Kinder und Erwachsene.) M. Bockhorn.

141. **How to Make the Most of Vacations.**—Bockhorn urges physicians to realize better the opportunities afforded by the vacations of the families in their charge, to enable the "resorters" to utilize to the full this welcome change. The physician may deem it best for the children to be separated from the parents for a time, or for one child to be separated from the rest. Children who are nervous, those who stutter, and both children and adults who have bad breathing habits, can be trained in better habits during the vacation.

Children are usually such imitators that even a brief course of training may do wonders. Bockhorn practices in a seaside resort and for the last four years has given summer courses out on the dunes in correct speaking and breathing and the use of the voice in general. It is remarkable, he observes, that so many persons who have to use their vocal organs a great deal never give a thought to perfecting the technic of its use. By his courses he has enabled some to resume their teaching or other career which they had had to give up on account of their voice failing, or asthma or other disturbance.

147 *The Chemistry of the Stomach with Cholelithiasis and Its Importance in Treatment. L. v. Aldor.

145. **Complications of Gastro-Enterostomy.**—In Decker's case fistulas had developed uniting stomach and jejunum, jejunum and transverse colon, and between the colon and stomach. The stools were clay colored. He broke up the adhesions and sutured the perforations, restoring the patient to health.

147. **Stomach Complications with Gall-Stones.**—Aldor recalls that nearly eight years ago he published his experiences in about a hundred cases of cholelithiasis without jaundice in over half of which he had found signs of a catarrhal affection in the small or large intestine or both. His examination of hundreds of similar cases since has confirmed the frequency of chronic intestinal catarrh with cholelithiasis, suggesting some causal connection between them. He here reports almost similar findings in respect to the stomach. Normal conditions of gastric secretion were found in only 18 per cent. of the 82 patients; hyperacidity in 39 per cent.; subnormal or no acidity in 42.6 per cent. The latter condition seems to be the result of the severe affection of the gall-bladder abolishing its function. The loss of gall-bladder functioning possibly modifies the composition of the bile as well as its mode of outflow. Bile in the gall-bladder is nearly ten times more concentrated than bile which drips directly from the liver into the intestine.

For these and other reasons enumerated, it seems evident that the gall-bladder is more than a mere reservoir for the bile, and the loss of it often entails severe and irreparable disturbance in gastric secretion. In a certain proportion of other gall-stone cases, chronic gastritis is responsible for the disturbance in gastric secretion. In this class of cases the symptoms on the part of the stomach keep up more or less most of the time, while in the other group they subside more or less during the intervals between the attacks of gall-stone trouble.

It is very important in treatment to discriminate between the cases with catarrhal affections and those without, as the measures appropriate in one may be directly injurious in the other. When the subacidity results from loss of gall-bladder functioning, hydrochloric acid is indicated, 25 or 30 drops in water half an hour after meals. This does not supply the natural amounts of hydrochloric acid, but it is enough to give the stimulus for pancreas secretion. When it is a question of chronic gastritis, with large amounts of mucus, rinsing out the fasting stomach has often had a surprisingly favorable action. Discovery of impairment of the gastric secretion with nothing else to indicate chronic gastritis, testifies to severe changes in the biliary apparatus, especially in the gall-bladder, and thus betokens a graver prognosis from this point of view than the gastritis cases.

148. **Treatment of Fistulas into Parotid Gland.**—Leriche cured an absolutely intractable fistula left from a stab-wound by exposing the auriculotemporal nerve, loosening it up back to the condyle process and then slowly twisting up its central end, pulling on it and tearing out a stretch about 4 cm. long. The secretion ceased completely in a few days and the fistula soon healed. He has applied this operation in three cases to date. (See Abstract 85 in The Journal, April 11, 1914, page 1203.)

149. **Operative Treatment of Spastic Flat-Foot**—Fischer and Baron give an illustrated description of an amplification of Tubby's operation. A strip of tendon 6 or 8 cm. long is cut from the peroneus longus and a shorter piece from the peroneus brevis. The longer piece is then used as a brace to hold the foot in good position. One end is slit and one of the halves is worked through a tunnel bored across the side of the scaphoid. The two halves are then sutured together, forming a kind of handle to the scaphoid. The strip is then brought upward under the skin and fastened to another tunnel bored across the side of the tibia just above the malleolus. The scaphoid bone and hence the whole foot can then be held in normal position by tightening the connecting brace.

RECOMMENDATION AS TO SANITATION CONCERNING EMPLOYEES OF THE MINES ON THE RAND MADE TO THE TRANSVAAL CHAMBER OF MINES

W. C. GORGAS, M.D.

Surgeon-General, United States Army; Chief Sanitary Officer, Isthmian Canal Commission

WASHINGTON, D. C.

At the invitation of the Chamber of Mines, I arrived in Johannesburg Dec. 3, 1913, to make investigations into the cause of the high death-rate from pneumonia among the native laborers working in the mines of the Rand. As a result of this investigation I was asked to recommend such measures as may appear necessary for the reduction of the death-rates and the improvement of the general sanitary condition of the mines and compounds.

For this purpose I was assisted by Major Robert E. Noble, Medical Corps, United States Army, general inspector, Department of Sanitation, Isthmian Canal Commission, and Dr. Samuel T. Darling, chief of the Board of Health Laboratory, Department of Sanitation, Isthmian Canal Commission.

In investigating this matter I find that the mortality among employees has been very large.

The reports of the Native Affairs Department show that for natives employed in mines and industrial works in the proclaimed government district of the Transvaal during the year 1903, the death-rate was 71.7 per thousand. This high death-rate has been steadily dropping till the present time. During the year 1912, for about 300,000 employees in the same area, the rate was 26.84. This rate is still very much too high, as we are considering men in the prime of life.

The death-rate among the negro employees working on the Panama Canal during the same year was only 10. Still this drop from 71 per thousand to 26 per thousand in the course of nine years is most encouraging.

On analyzing the reports for 1912 of the Native Affairs Department, Appendix 2, page 79, we find that the total death-rate was 22.6 for diseases. The four highest diseases were pneumonia, phthisis, meningitis and enteric fever, giving us rates of 9.8, 5.4, 1.3, 1.1. These four diseases are all more or less infectious and contractable. If they could be entirely eliminated, the rate for 1912 would be reduced to 5.0 for all other diseases. While entire eradication of these diseases cannot at present be accomplished in this or any other community, probably, by proper hygienic measures, a very appreciable reduction could be accomplished.

PNEUMONIA

First, let us consider pneumonia. It varies very greatly in the different mines. It also varies greatly as to the locality from which the natives come. Among natives from the British Nyassaland Protectorate it is highest. Among the natives from the Cape Province it is lowest

Taking the report of the Native Affairs Department from 1909 to 1913, we find that February had the lowest rate with an average of 9.56, and May the highest with 12.64. Taking three consecutive months, we find that January, February and March have the lowest rates with an average of 10.02. We find that October, November and December have the highest rate with an average of 12.28. Ordinarily, pneumonia causes its greatest mortality in the cold winter months. This does not seem to be the case here as far as the mortality-tables bear evidence; but these tables are obscured, as far as this particular point is concerned, from the fact that the tropical native was not brought to the Rand during the winter months. It is no doubt the case here, as it is everywhere else, that the incidence of pneumonia is greater during the winter than during the summer months.

Dr. Maynard has worked out tables which show this to be the case.

The pneumonia rate varies widely also in different localities. Among natives not working in mines in the city of Johannesburg, the rate was 1.20 per thousand for the year 1912. In the new Goch mine, the rate among natives was 16.71. In the Municipal Location at Klipspruit, the rate among 750 natives over 18 years of age, extending over a period of three years, was 1.37. This is the same class, and also age, as the men in the mines.

Pneumonia is a disease in man due to infection by a particular organism—the pneumococcus. Individuals and races differ widely in the degree in which this organism affects them. Some races, like the white, resist infection strongly. Others, like the negro, have less resistance. Those races with less resistance acquire a much higher degree of resistance after long exposure to the infection. The negro when brought into a community in which pneumonia prevails acquires nearly as high a degree of resistance as the white man. If we take 100 white men and examine them, we shall find that twenty or thirty have virulent pneumococci in their throats. When one of these individuals becomes much depressed from any cause, such as exposure to cold, starvation, severe sickness or any constitutional strain, he is liable to develop pneumonia. If we bring the unacclimatized negro into contact with such persons or other infected negroes, he gets the pneumococcus in his throat and secretions in the same way. The white man, by long exposure to this pneumococcus, having constant slight colds, sore throats, etc., has acquired more or less immunity to the organism. The negro, when he first comes in contact with the pneumococcus, has none of this immunity. Expose the two men to the same depressing agency, give them both a bad cold, for instance, and the white man, through his immunity, resists the pneumococcus, while the negro does not. The organism obtains an entrance in the latter case, and the man succumbs to pneumonia.

If we take a community composed of persons who have had little exposure to the pneumococcus, we shall find a high mortality-rate from pneumonia. If the community is made up of persons who have had prolonged exposure to the pneumococcus, we shall find a low mortality-rate from pneumonia.

We find for the year 1912, that the 21,000 tropicals had a death-rate from pneumonia of 26.30. But the 199,000 non-tropicals had a rate of 8. In general, the tropical is the non-civilized native who has had little contact with the white man's diseases, and the non-tropical, the native who has had more or less contact with civilization—and the white man's diseases.

In general, therefore, a community which has had a large proportion of tropical natives will have a high pneumonia death-rate, and a community with a large proportion of non-tropical natives will have a low pneumonia death-rate.

This is a general rule to which there are individual exceptions, as is always the case in infectious diseases.

It is everywhere asserted on the mines by those in a position to know, that the old "boy" has a very much lower rate of pneumonia than the new "boy." I have no doubt that this is true. All the facts that we can collect point in that direction. On the Isthmus the new "boy" had a four and a half times higher rate than the old "boy." Dr. Maynard, in his excellent report on this subject, finds that taking the pneumonia among natives on the mines, from the first to the eighteenth month at work, the rate is: 15.83 per thousand during the first six months, 9.01 during the second six months, and 5.31 during the third six months.

Furthermore, in confirmation of this, in one of the mines especially investigated with regard to this point, it was found that a marked preponderance of deaths from pneumonia occurred during the first few months of service in the mines. All the deaths from pneumonia during the year 1913 at this mine, according to the month of service in which they occurred are given in Table 1. The very extensive and useful statistical tables furnished us by the Witwatersland Natives' Labor Association show that during the year 1912, 2,031 deaths from pneumonia occurred among native laborers. Of these deaths, 1,199 occurred among men who had been on the mines less than six months. In 1913, 1,668 deaths occurred from the same cause. Of these deaths, 981 occurred among men who had been on the mines less than six months.

The uniformity with which pneumonia attacks preponderatingly the new boy, or recently arrived native, is as pronounced here on the Rand and in Rhodesia as it was on the Isthmus of Panama, and this seems to be the only generalization of epidemiologic value yet drawn with regard to the incidence of pneumonia.

This indicates that the question of immunity is the most important element in the causation of the death-rate. This being the case, what sanitary step can be taken to decrease the rate?

In the construction of the Panama Canal, in its incipiency, we had much the same trouble with pneumonia among the negroes that is experienced with the negroes in the mines in the Transvaal.

The bulk of our working force is composed of negroes brought from the West India Islands, mostly from Jamaica and the Barbados. In August, 1913, our total force was 58,500, of whom 46,000 were negroes and 12,500 white men. In 1906, our force was an average of 21,000 negroes and 5,400 white men. Among these negroes we had 396 deaths from pneumonia, a rate of 18.74 per thousand per annum. In 1907, we had an average of 28,600 negroes and 10,700 white men. Among these negroes we had 304 deaths from pneumonia, a rate of 10.65. In July, 1906, with a negro force of 22,989, we had 84 deaths, which gives us an annual rate of 43.41.

The death-rate for pneumonia among the black employees of the Isthmian Canal Commission in 1906 was 18.74 per thousand, which is higher than the death-rate for this disease among native employees in the Proclaimed Labor District of the Transvaal for any year since 1909.

The rise in pneumonia, with us, commenced in October, 1905, and increased until July, 1906, when it reached its maximum, from which time it slowly decreased.

Our death-rate from pneumonia for the succeeding years among the negroes is given in Table 2.

TABLE 2.—DEATH-RATE AMONG NEGROES

Year	Death-Rate	Year	Death-Rate
1906	18.74	1910	1.66
1907	10.61	1911	2.24
1908	2.60	1912	1.30
1909	1.66	1913*	0.42

* First eight months.

We appointed a board to examine into this matter. This board gave a great deal of time and attention to the work and went into it very carefully. It found that no particular house or town had a continuously high rate. The rate would vary from time to time. This indicated that the variation was due to a varying factor of infection, and not to location or surroundings.

With regard to seasonal incidence, we found that the pneumonia in Panama increased from the beginning of the dry season of 1907, being the greatest toward its end, with 124 cases in April, the driest month. It diminished in number in May and June, which are wetter months, but rose again in July, which was as wet as June. It was decidedly worse in the dry season of 1907 than in the wet season of 1907; but this was opposed to its general course for 1906, for the greatest number of cases of pneumonia appeared during some of the wettest months.

Our men worked continuously in the rain, and came home soaked through at night. The majority of them were so poor that they did not have a change of clothing. They therefore slept in their wet clothes. The board tabulated those who had one suit of clothing, and those who had more than one suit. The results showed no relation. The men who slept in dry clothes had as much pneumonia as those who slept in wet.

Our barracks were arranged with tiers of bunks, and were so ventilated that the top bunk had much more draft than the others. The men were tabulated as to sleeping in top bunks, or lower bunks, with no result. The rate of pneumonia in the top bunk was no greater than in the lower.

Altitude had little effect. Though there was not much difference in our camps in this respect, some were at sea-level, others in the hills on the divide at between two and three hundred feet elevation. There was no constant difference between such camps. Some camps at sea-level had very high rates, others at the same altitude low rates. Some camps in the hills high rates, others low.

The only difference in susceptibility was shown to be governed by the length of time that the laborer had been on the Isthmus. This is shown in Table 3, which indicates that the same number of men over three months on the Isthmus who furnished two cases of pneumonia would give nine cases if they were men who had had less than three months' residence.

TABLE 3.—SUSCEPTIBILITY OF NEW MEN AND OLD MEN *

Month	No. New Men	No. Old Men	Colored Pay-Roll	Cases, New Men	Cases, Old Men	Ratio No. New Men to Old	Ratio of No. of Cases New Men to Old	Comparison of the Two Ratios
March ..	6,559	20,655	27,214	55	29	1:3.14	1:0.52	6.04

Number of old men............92,331

The board found that the pneumonia was four and a half times as high among the men who had been on the Isthmus less than three months as it was among men who had been on the Isthmus more than three months. We argued from this that the question was one of immunity; that the negro who had been on the Isthmus three months became acclimatized, and acquired a certain sort of immunity. We probably get the organism slowly, and thereby acquire immunity, whereas the man who developed pneumonia had not been exposed long enough to acquire immunity when the exciting causes came along.

The arrivals on the Isthmus of steerage passengers from 1905 on are shown in Table 4.

The number of steerage passengers is a fair measure of the number of negroes coming out to the work.

We see that there is a relation between the number of newcomers and the incidence of pneumonia in 1906 and 1907. At that time all laborers were housed in barracks provided by the Isthmian Canal Commission. From 1908 to 1913 the incoming negroes were from the same areas as those who came in 1905, 1906 and 1907. During the whole period, laborers were returning to their homes and later returning to the Isthmus for work, just as is the case on the Rand. The only difference is that on the Isthmus there was for each year a decided increase of arrivals over departures, which shows that there was each year a considerable number of non-immunes arriving on the Isthmus, yet with a decrease in the incidence of the disease. The fall in death-rate from pneumonia was coincident with allowing laborers to leave the barracks provided by the commission and build for themselves cabins on the hills, or to live in the towns of the Canal Zone, and the bringing in of their families. Table 4 shows the incoming and outgoing steerage traffic with the net increase in population.

TABLE 4. QUARANTINE REPORT OF ARRIVALS AND DEPARTURES OF STEERAGE PASSENGERS FROM AND TO FOREIGN PORTS

Year	Arrivals	Departures	Increase
1905	24,202	12,904	11,298
1906	34,433	16,694	17,739
1907	36,438	17,900	18,538

1909	22,851	13,445	9,406
1910	21,851	17,319	4,532
1911	21,520	17,272	4,248
1912	21,298	19,911	1,387
1913*	21,573	14,969	6,606
Totals	230,771	147,093	83,678

* Eight months only.

Among the 24,000 negroes coming to the Isthmus in 1905, there was a very small proportion of persons who had been to the Isthmus before, whereas among the 21,000 who came in 1912 there was a very large proportion. In 1908 our pneumonia dropped to 2.60 per thousand, and since that time it has continued to fall, though we have continued to bring in a considerable number of new employees.

During the first few years on the Isthmus, we housed our negroes in barracks containing about eighty-four men each, and of such dimensions as to give them about 30 feet of floor-space. This is ordinarily considered very crowded. In 1907 we allowed our negro laborers to scatter out along the line of the Canal, build each man his hut, with a small cultivable piece of land, and bring over his family In 1910 our negro force was 37,000. Of this force, only about 7,000 lived in barracks; the other 30,000 lived in their own establishments. To this fact of scattering I attribute the disappearance of epidemic pneumonia. I explain it in this way:

It is a well-recognized fact in military hygiene that overcrowding of a barrack is coincident with inflammation of the upper respiratory passages, which at times becomes epidemic. This was the case on the Isthmus of Panama, and doubtless is the case on the Rand. Non-immunes crowded into barracks would in the same manner develop inflammation of the upper respiratory passages, in many cases due to the pneumococcus, which inflammation would afford a portal of entry for the pneumococcus, resulting in some persons in lobar pneumonia, and in others in a certain amount of immunity. If we have eighty-five men in a crowded barrack, and the pneumococcus gets in, the probabilities of its spreading to the other men are considerable. If the pneumococcus establishes itself in a man living in a hut alone, or with his family, it is not apt to spread to the men with whom he works, and with whom the contact is not intimate. I am satisfied in my own mind that the scattering of our negroes was the chief cause of our sudden and permanent drop in pneumonia on the Isthmus.

Other causes no doubt contribute to it. The next most important, we think, is acquired immunity, such immunity as the old boy would have as compared with the new boy. It is self-evident that the proportion of old boys to the new was much larger in the force in 1909 than it was in 1906.

We are at present endeavoring to get 1,500 new tropicals with the idea of trying the matter by experiment. Our wish is to take some one mine, place the whole number at this mine, put 500 in huts, of the remaining 1,000 inoculate 500 against pneumonia, and place the whole 1,000 in barracks. Such an experiment would not be at all conclusive, however, if tried for only a short time. For instance, the barrack in which the inoculated lived might become infected, and the other barrack and the huts remain uninfected. In this case all the pneumonia might occur among the inoculated, not because of the inoculation, but because of the accident of their infection. The experiment, however, would be useful as far as it went. If continued for a long enough time, and in a considerable number of instances, fewer men ought to become infected in the huts than in the barracks.

I recommend that the question of immunization for pneumonia as recommended by Sir Almroth Wright be more carefully looked into. So far the evidence on the subject is more or less contradictory. As tried on the Rand the inoculated do not show any greater protection than the controls, but as used at the Premier Mine in 1913, the results seem very striking. In 1912, the 17,000 inoculated had a death-rate from pneumonia of 6.89 per thousand, and the 6,700 controls a death-rate of 17.72 per thousand. The inoculated and controls were selected at random, and I can see no reasonable explanation for the marked difference between the pneumonia death-rate of the inoculated and that of the controls, except that the inoculation gave a large degree of protection to the inoculated. It has been urged that a large proportion of the vaccinated might have come, purely accidentally, from regions in which the immunity of the native was high, and a large proportion of the controls from regions in which immunity was low. As a mathematical proposition this is true. There is one chance in a hundred that this might be so. But as a practical proposition it can be thrown out and not considered.

In 1910, the death-rate from pneumonia was 27.72 per thousand; in 1911, 30.99; in 1912, 9.83, and in 1913, 7.63.

They received their last tropicals in 1910. Since that time, as was to have been expected, the death-rate has dropped. In 1913 they vaccinated all their men, and their death-rate dropped to 7.63. It is rather against the Premier that their death-rate from pneumonia in 1913 (7.63) should be just about the same as the average death-rate from pneumonia on the Rand from natives south of latitude 22—8 per thousand.

Dr. Darling has suggested that the vaccine used at the Premier may be from organisms of a different strain from those used on the Rand. This has actually occurred in the use of vaccine for typhoid fever. A body of men protected by vaccination against typhoid fever has been found *not* to have been protected against paratyphoid.

It would be useful for the Chamber of Mines to continue the experimental inoculation against pneumonia, using the different strains of pneumococci. If we had such a vaccine, as the results at the Premier seem to show, then the question of the employment of the tropical natives would be at once solved. I recommend that in future when vaccinating natives, one-half be kept as controls. By this method you would soon arrive at positive results.

In considering preventive measures it must be borne in mind that the causative agent in pneumonia is the pneumococcus, an extremely delicate micro-organism; when exposed to external influences, such as sunlight and drying it is killed in a few minutes, but when resident in the respiratory passages of those infected it lives for weeks and months.

Persons recovering, or having recovered, from pneumonia may, and usually do, carry virulent pneumococci in their mouths and respiratory passages for long periods, and may infect others indirectly by means of their sputum, or by infecting the drinking- or eating-utensils used by several persons in common, or by infecting the common water-tap or cup. It has been observed that natives when drinking from the water-tap place it in their mouths, and in this way may leave a moist film of infected spittle on the tap to be taken up by the next person using the tap. In the mines, one tap has to serve for many laborers on the level, and personal observation has shown the facility with which a line of thirsty natives may become mutually infected.

Not only are pneumococci transferred in this way from persons who have recovered from pneumonia, but it is most probable that pneumococci are acquired similarly from persons suffering from the "common cold," tonsillitis and other forms of inflammatory disease affecting the upper air-passages.

It is highly desirable, therefore, that means should be used to prevent as far as possible such conveyance of infection as is indicated above. This might be done effectively and economically by means of some of the well-known types of "bubbling" fountain, or protected taps. These taps prevent the dissemination not only of pneumonia, but also of tuberculosis and syphilis.

TUBERCULOSIS

Next let us consider tuberculosis. This disease is far too high among native miners. The report for 1912 shows that the total rate for all native miners was 5.65 per thousand for pulmonary tuberculosis. The rate at Panama, for the same class during the same year, was less than 1 per thousand. The rate for London, total population, men, women and children, was 1.03 per thousand for 1911, and for New York, 1.67 per thousand for 1911.

In addition to the deaths of natives from pulmonary tuberculosis, there is a high percentage of deaths from other forms of tuberculosis among the native laborers, as tuberculosis of the intestines and abdominal viscera.

During the year 1912, 1,168 patients with tuberculosis in all its forms, were repatriated by the Witwatersland Natives' Labor Association. It is not a high estimate to say that half of these (584) died during this year. During the same year thirty-three patients with tuberculosis died in the W. N. L. A. compound.

Judging from findings of necropsies witnessed by Dr. Darling, I am of the opinion that a considerable number of cases of deaths reported as occurring from pneumonia, result really from tuberculosis. This, under the circumstances, is an unavoidable clinical error. The actual number of deaths from tuberculosis for the year 1912 among your 156,534 natives is probably 885 reported, 584 deported, 33 in compound, and 200 error in diagnosis, a total of 1,702.

This gives a death-rate for tuberculosis in all its forms of 10.87 per thousand per annum, of the average working force of 156,534 natives, so that the death-rate from tuberculosis in all its forms is as a matter of fact considerably higher than 5.65 per thousand for 1912, and 4.80 per thousand for 1913, as shown by the reports supplied me by the Chamber of Mines.

Estimating the deaths from tuberculosis in the same way as above, we find that in 1910 we had among natives 1,001 by report, 268 repatriated for last six months of year, 51 in compound, and 200 by error, a total of 1,520, which would give us a rate of 8.85 per thousand. In 1912, estimating as above, we have a rate of 10.87 per thousand. I am inclined to think that for the future, present conditions continuing, tuberculosis will cause you more trouble among natives than does pneumonia at present.

Overcrowding plays just as important a part in the spread of tuberculosis of types other than pulmonary tuberculosis, as it does in the pulmonary type. The same measures for its control are applicable.

Tuberculosis is caused in man by a well-known micro-organism, the *Bacillus tuberculosis.* This bacillus can be transferred from person to person in many ways. The most common way is by the sputum of the diseased person. This sputum is expectorated, dries, becomes pulverized, and the bacilli are blown about, and enter the lungs of the well person. Or, without drying, it can get on the hands of others, and thus be transferred to the mouth and enter the system. The greatest preventive measures are therefore concerned with the care of the sputum. White miners having tuberculosis should be eliminated; if elimination is not possible, they should be supplied with spit-cups, or cloths into which they can expectorate, and be individually furnished with literature explaining the danger of promiscuous expectoration. With the native miner any attempt of this kind would be impracticable. Careful routine medical examination should be made of the sick, and when a man is found to have tuberculosis he should be excluded from the mines. As far as the native is concerned, the most important single measure is that recommended for pneumonia, that is, scattering, and in the same way as recommended for pneumonia.

Disinfection in the dwellings of the tuberculous is useful and important, and should always be resorted to.

No argument is necessary to prove that by reason of close personal contact, if we have a hundred men in a room, each with 25 feet of floor-space, infection would spread more rapidly and generally than if we had fifty men in the same room having 50 feet of floor-space. It is equally evident that a larger number of persons would be infected, when infection was introduced into a room in which a hundred persons were living, than when introduced into a room in which six persons were living, the floor-space per capita being the same in the two cases.

Tuberculosis is a disease that can be particularly combated by fresh air, sunshine, cleanliness and roomy quarters.

MINERS' PHTHISIS

Miners' phthisis is a disease which has so far been steadily increasing on the Rand. The reports for 1903 show a rate of 0.05 per thousand, and that for 1912 a rate of 0.10 per thousand. This disease is essentially a silicosis, and is caused by particles of silica getting into the lung-tissue, through respired air, causing chronic inflammation, the tissue thickening until finally a considerable portion of the lung is destroyed for respiratory purposes. This condition of the lung brings about a low state of local vitality, so that an organism like the tubercle bacillus easily finds lodgment. At present on the Rand most persons with miners' phthisis die from an incidental tuberculosis implanted on a silicized lung, rather than from silicosis itself. The hygiene of this disease is obvious, that of laying the dust, so that particles of silica will not be floated in the air where they can be breathed. Some form of water-spraying apparatus is now very generally used on the Rand. I advise that such measures be generally and carefully enforced and extended. I believe that they will soon reduce miners' phthisis to a minimum.

CEREBROSPINAL MENINGITIS

Cerebrospinal meningitis is a disease that at times causes considerable mortality among native miners on the Rand. This is an infectious disease whose organism, so far as we know at present, is spread from person to person by crowding and contact. Scattering would also be the most effective sanitary measure against this disease, in addition to the general measures of cleanliness, air and light already referred to. Disinfection is probably more useful in this disease than in either of the diseases previously discussed.

TYPHOID FEVER

During the last four years you have lost 310 men on an average by death from typhoid fever. During 1912 you had 234 deaths in this class of employee, and during 1913, 249. Typhoid fever by vaccination is as preventable as is small-pox. This death-rate could be entirely wiped out at once. With your present organized force of medical men it would be neither difficult nor expensive. The vaccination itself causes nothing like the trouble to the person vaccinated as does the vaccination for small-pox. In general, there is almost no reaction, soreness or effect of any kind.

I recommend that all native employees and such of the white employees as so desire, be vaccinated for typhoid fever.

HOUSING THE NATIVE

The most serious sanitary defect that I notice in the mines on the Rand is the manner of housing the native. The quarters are much too crowded. He has in general 200 cubic feet of air-space, which would give him 14 feet of floor-space. The general objection to such crowding is that it causes the respired air to become vitiated. My great objection to such crowding is that it forces the occupants into close personal contact, and therefore largely increases the spread of any infectious disease. This applies particularly to pneumonia, tuberculosis and cerebrospinal meningitis. A large aggregation of men in one room is objectionable in itself. It is evident that if infection is introduced into a room containing a hundred men, it is more likely to affect a larger number than if introduced into a room containing six men.

In the French army they allow about 50 feet of floor-space to a man. Recently they have largely increased their army, which has caused crowding in their barracks. I see it stated in the newspapers that epidemic pneumonia is prevailing among the men, and that the French sanitary authorities attribute the epidemic pneumonia to this overcrowding.

I am satisfied in my own mind that the scattering from large barracks into single huts and small rooms was the important measure in its effects on pneumonia on the Isthmus. For the sanitation of pneumonia I would urge a similar measure on the Rand. Place your negro laborers in individual buildings, and bring in, and place with them, their families. This measure, I feel confident, would result with you as it did with us. In the course of about a year it reduced our pneumonia death-rate from 18.40 per thousand to 2 per thousand. It would probably reduce your present rate of 15 per thousand (the highest pneumonia monthly rate for 1913) to 2 per thousand. If this is not feasible at present, the nearest approximation to it should be attempted.

What is at once feasible, it seems to me, is to extend your family locations. At present all the mines have such a location where the native lives with his women and children. Wherever I have examined into these locations the pneumonia rate and the general death-rate are low. They are always among the very best class of native rates on the Rand. We recently examined into the condition of the city location at Klipspruit. Here about 2,800 natives, men, women and children, live in neatly constructed single dwellings, more or less separated, from 50 to 200 feet apart. The whole village, both inside and outside the dwellings, was well policed, and presented a clean and attractive appearance. We had the superintendent, Mr. Smith, go over the records, selecting the male native, over 18 years of age, and give us his records both for pneumonia and for general rate. We found that for the past three years, with an average of 750 natives of this class, the pneumonia death-rate had been 1.37 per thousand, and the general rate 9.17 per thousand, while the native rate for pneumonia in the mines on the Rand for the same year (1913) was 10.05.

It is a very striking coincidence that whenever we find the native on the Rand living as he does on the Isthmus of Panama, his health-rates are approximately as good as they are on the Isthmus. When the negro on the Isthmus lived in large barracks, as does the native in general on the Rand, his health-rates were fully as bad as those on the Rand. Wherever I have inquired, the compound manager has told me that he has more applicants for married quarters than he can accommodate, and that if he had more buildings he could fill them. Let each mine therefore put up cheap but comfortable buildings, as they find they have need for them. The native hut, of which Mr. Lloyd, your superintendent of recruiting, furnished me drawings and specifications, strikes me as being excellent. It has a circular wall with thatched roof. In this type of hut, concrete floors and glazed windows I consider quite unnecessary.

I saw a large village of these huts at the Arcturus mines. They were attractive and neat in appearance, complied with the needs of sanitation, and were economical in construction. In extending locations, it would be better, from a sanitary point of view, to erect huts rather than to extend the present buildings.

In extending these locations an eye should be had to the future. They should be laid out in streets and blocks with a view to eventually putting in a waterborne sewerage system.

Eventually, in this way, a considerable portion of the force could be placed in these villages, and the barracks mainly used for the unmarried men. This would begin at once to give more room in the barrack for the highly susceptible new boy. As the barracks ceased to be needed for the unmarried native, they could be slightly rearranged for native married families. This was very satisfactorily done at Panama. As we ceased to need the barracks for our unmarried negro laborer, we transformed them economically into comfortable married quarters.

A native labor force living with families near the mines would be more stable and contented than the present force. They would be old and experienced men and therefore more efficient, and from all points of view more economical and satisfactory to the mine manager than the present force.

The economy of this method of housing native laborers might be emphasized by calling attention to the fact that recruiting men costs about $5,000,000 (£1,000,000) per annum. The greater part of this expense can be saved by the construction of locations—such as Klipspruit—or building huts of the general type of those erected by natives at their kraals.

A force of married men living in such a location would be a permanent force of skilled workmen, always available as a source of labor for the mines.

A nominal charge for such huts should be made, such a charge as would pay for the hut, say in ten years, and also keep the huts in repair. Such a location would be self-supporting and would correct the unsatisfactory health conditions of the compounds by giving more floor-space per capita to those who continue to live in them.

Public sentiment will not approve the keeping of a large body of semisavage laborers in the community in such conditions as obviously to foster sexual crimes. Both the public and the laborer will insist on the native having his women and children. If the laborer cannot have his family with him at the mines, he will, as the country develops, seek other employment where he can have them.

On the order of the government, recruiting among the tropical natives ceased last March. If we were considering the sanitation of the tropical native alone, I should still more strongly urge scattering, as much as possible, as the proper sanitary measure for him against pneumonia. This dispersion I should bring about, if possible, by putting him in a hut with his family. If this were not possible, I should put him in huts, without his family, arranged so as to give him 50 square feet of floor-space. If huts were not possible, I should put him in barracks with the smallest rooms I had, arranged so as to give him 50 square feet of floor-space.

In general, the care of the compound yards showed everywhere neatness, cleanliness and commendable care and discipline; but when we came to examine the interior of the native living-quarters the very opposite was the case.

Food was always present in dirty and unkept vessels in considerable quantities; old clothing and wearing-apparel of all kinds, soiled and dirty, was littering up everything, and litter of all kinds was stowed away under the sleeping-platforms. I was told that discipline and cleanliness were not enforced in the sleeping-quarters from the fact that the authorities did not wish to interfere with the natives to such a degree as to make them dissatisfied. This is a very good general rule, and a population of the class of the ignorant native miner should not be worried with too many and exacting sanitary regulations. Indeed, I do not see that much in the way of correction could be done, even if the native cooperated, in the present crowded condition of the barracks. But give each man 50 feet of floor-space, and he can have an individual bed and box of some kind in which he could keep his personal belongings. It would then be no hardship to require him to keep his belongings to his own bed and in his own box.

If a number of small sheds, inexpensive in construction, and convenient to the sleeping-rooms, were erected around the compound, it would be no great hardship to require him to eat his food under this shed. In the receiving compound at Johannesburg, the native is required to eat his food on a concrete platform, and no food is allowed in the living rooms. Dr. Turner tells me that there is no particular objection on the part of the natives.

I am confident that if the sanitary necessity of keeping the barracks in a cleaner condition was considered, the details could be worked out gradually so as not to interfere to any great extent with the habits and customs of the natives.

A commendable effort is being made generally to correct this condition by cleaning up, taking out refuse, destroying bugs, whitewashing, etc. But this must be done (in the nature of things) very often. In the best-kept quarters which I have seen this is done about once a month, but in a few days conditions are as bad as ever. It is not feasible to make any considerable improvement in present conditions as long as the barracks are as crowded as they are, and as long as the men are allowed to eat and keep food in their sleeping-quarters.

I recommend that each native be allowed 50 square feet of floor-space; that he be furnished with an individual bed, and an individual box in which to keep his belongings; that the barracks be divided into smaller rooms to contain not more than from twelve to fifteen men; that no food or utensils of any kind be allowed in the dormitories, and that eating-sheds be erected about the compound, located conveniently to the dormitories. A good many of the men at present keep their food from meal to meal and consume it between times. They also use the mealie porridge for making fermented drinks. If it is necessary to allow this, to each native who asked for it, a locker in the eating-shed could be assigned. The expense of such changes would not be large. The increase in floor-space would cause a large expenditure, if the force were as full as it was a year ago. If you encourage your married locations, some room would be gained in the barracks in this way. The reforms could be carried out gradually. Those compounds could first be selected in which the death-rate was high. There are a considerable number of compounds in which the death-rate has been low for a number of years. They are frequently the old compounds which the native prefers, and therefore they contain a larger number of old boys. In all the cases into which I have examined the crowding there was not so great.

These two conditions, namely, the lesser crowding and the greater proportion of old boys, generally explain the better health-rates. Such compounds I should not interfere with. In this way gradual improvement could be brought about at no very large yearly outlay.

DIET OF THE NATIVES

The ration is another thing that has impressed me very strongly in inspecting the various mines. I have never seen so large a proportion of the ration supplied by one article as is here supplied by mealie meal. The two chief components of the daily ration are 2 pounds of mealie meal and $5\,^{85}/_{100}$ ounces of meat. This I think, a great deal too large a proportion of the carbohydrates for men doing the hard manual labor that the natives do. The mealie meal might be reduced, and the meat and other articles increased.

A soldier's ration in the British Army is 16 ounces of bread, 12 ounces of meat, and also an allowance of 3 pence per day for vegetables, and other articles. A miner does very much harder labor than the soldier. I think that his diet should be at least as good.

On the Isthmus we had a great deal of trouble as to rations. There was no particular disease among our laborers that we could attribute to diet, but they seemed to be underfed, and there was constant complaint. The whole matter of food was satisfactorily settled both for the negro and ourselves when the families came and when we established commissaries for the sale of food at cost. The negro then bought what he liked in such quantities as he wished, and his wife cooked it in the manner to which they had been accustomed. At the Premier mine they have three systems of feeding going on at once. The native can either eat his food at the regular mess, buy such cooked food as he likes, or buy food and cook it himself.

At the Kimberly mines the system of food-supply is altogether that of allowing the native to buy his own food. It seemed to be very satisfactory. This would be an excellent system of feeding to adopt generally, although I prefer our system on the Isthmus, where food is supplied the native at cost. The object of this measure is to give him an abundant food-supply in such a way that he can vary it as his tastes suggest. If you attempt to make a profit on food, you by so much defeat the object of your measure.

I am inclined to attribute scurvy to the large amount of mealie meal in the ration. It has been found that beriberi is caused by making polished rice the almost exclusive article of diet. It is due not to the rice itself but to the fact that the rice is polished. In polishing, the pericarp is rubbed off, and this pericarp contains substances that are necessary in the body economy. Mealie meal, as used on the Rand, has a similar outer coating removed in the process of mill-ing. Dr. Macaulay goes into this question, and brings some very strong evidence to prove that scurvy is due to having such a large proportion of the diet consist of the bolted mealie meal. If this is the case, it can be corrected easily and economically by having the meal properly prepared. This question should be investigated further.

On the Isthmus of Panama in 1906, each man bought his own food from a poorly supplied market, at a very high price, and cooked it himself. In 1908 he bought from a well-stocked market, at cost price, and had some one to prepare his meals.

We first started having each man take care of himself as far as food was concerned. Each laborer bought his uncooked food from the nearest native vender, and cooked it himself between working-hours This proved very unsatisfactory for several reasons. The laborer did not have time to collect his food and cook it between working-hours. He was also too much fatigued to do it properly. Our force increased so rapidly that we consumed everything that there was in the country. We then put up stores along the line, supplying food at cost, and also kitchens where it could be bought cooked at a reasonable price. This proved a distinct improvement over former conditions, but the matter of feeding was put on an entirely satisfactory footing, both to ourselves and to the negroes, by bringing the families over, and allowing each man to put up a hut for himself and his family.

Since that time we have had no trouble as to food for the negro, or dietetic diseases among them. Each negro now gets such food as he likes at cost, and his wife cooks it for him in the manner and quantities which he likes best. Present conditions as to food are entirely agreeable to both parties. The establishment of stores by the commission and selling at low price in no way interfered with opening of stores by private persons. Such stores existed in considerable numbers at all towns and were prosperous.

SEWERAGE AND WATER SYSTEMS

Another sanitary improvement completed at about this time was the introduction of sewerage and water systems. One of the prominent causes of death among our predecessors had been dysentery. Indeed, this disease is generally prominent in tropical countries.

Typhoid fever is another disease that we knew we should have to reckon with. In the hope of protecting ourselves against these two diseases we put in eight different water systems along the 50 miles of canal. Generally for getting water, we dammed the small streams near their source in the mountains, and piped the water down to the cities and villages along the line of the canal. About twenty sewer systems were put in at these villages. The sewerage systems were limited to the villages.

We see, therefore, that several things happened about the time of the disappearance of our epidemic of pneumonia.

The men were scattered from crowded barracks to individual huts in the hills, and houses in the towns.

An insufficient, poor, expensive food-supply, badly cooked, was replaced by one abundant in quantity, good in quality, cheap, and very well cooked.

Water-supplies and sewerage systems were everywhere installed.

It is an obvious axiom of both hygiene and economy that no unnecessary tax should be placed on the strength of the native laborer. With these objects in view, he should be conveyed to his place of labor, and away from it, with as little delay and as little exertion to himself as possible.

The present bucket system of disposing of night-soil should be replaced by a water-borne system. This is possible everywhere on the Rand above surface. This bucket system promotes the breeding of flies, and the transference of diseased fecal matter by these insects. The water-borne system would be economical as compared with the present bucket system. Several of the mines have at present partial water-borne systems. I commend particularly that of the Crown mines.

Where a water-borne system is not feasible I consider a properly constructed, fly-proof, pit-closet preferable to the present bucket system. It is more sanitary and less expensive.

Underground a water-borne system seems to be impracticable from a mechanical point of view. A vault system would be a decided improvement on the present bucket system, both from a sanitary point of view and from the point of view of economy. I mean by a vault system the excavating of a small vault and placing on it a fly-proof seat wherever a closet is needed. I should use no water whatever. Allow only in the vault fecal matter and urine. When the vault is filled, close the vault and move the seat to a new location, or empty the vault with an odorless excavator. I should empty the vault or move the seat as seemed most convenient and economical. Vaults that were located on the outer workings, and that were to be used less than a year, I should think could be more economically closed than emptied. Vaults that were located near the center of the workings, and were to be used for several years, might be emptied when filled. This should be determined purely from the point of view of expense.

There would be some sanitary advantage in closing a vault rather than emptying it. I think that from an administrative point of view it would be found more economical to close a vault and build a new one, rather than to empty it. The length of time that a vault would last would be determined by its size.

It has been objected that there would be leakage through cracks in the rock from these vaults into the mine below. There would be so little fluid, the urine only, that I do not believe this would be the case. If the deposit were found to be too fluid, this condition could easily be remedied by the use of dry earth or some similar drying material. I have seen this system used on a large scale in cities with little objection as to odor or inconvenience. The great sanitary objection to the present bucket system is against the daily handling and carrying through the mines of fecal matter, and the necessary fouling and disagreeable odors that go with such a system. The great sanitary advantage of a vault system in such locations as the mines is that the excreta are permanently disposed of as soon as deposited.

The economical disadvantage of the bucket system lies in the considerable expense of daily transporting the buckets to the surface, emptying, cleaning and returning, as well as the expense of plant. The only expense of the vault system would be that of originally digging the vault and then of closing it.

A system of septic tanks might be considered if it should be found more economical than the vault. I think that such a system could be planned so that there would be no objection to the effluent passing into the general drainage system.

THE FLY NUISANCE

I commend the effort at some of the mines to abate the fly nuisance by trapping and otherwise. All eating-houses, kitchens, dining-rooms, or wherever cooked food, or food, such as fruit, that is eaten uncooked, is exposed, should be well screened as a protection against these insects. In addition, traps, fly-paper and such devices as tend to destroy flies that have gained entrance to these places should be used. The present crusade against fly-breeding should be encouraged in every way. Such a movement is one of the best educators that I know of.

The disposal of garbage is generally satisfactory. It is in general dumped at some out-of-the-way place sufficiently removed from the mine so that the odors and the flies are not troublesome. I should recommend, however, the general use of crematories. The crematory system is generally more satisfactory than the dump, from the fact that it does away with fly-breeding and disagreeable odors. In many cases it is more economical from the fact that the haul is much shorter in the case of the crematory.

Alcohol for the native, I believe, is an unmitigated evil. It is in no way necessary for his health; in fact, it is always hurtful.

THE LIQUOR QUESTION

On the Isthmus we had our laboring force located on the line of Canal about 50 miles in extent. In this distance we had about twenty towns. At first we allowed as many liquor establishments as chose to pay the high license, $1,200 per year. As time went on we gradually abolished saloons in town after town, till last year, liquor-selling was finally abolished on all the Zone. Saloons were gradually abolished in district after district, generally at the request of the engineer in charge of the working force in that district.

The two Panama towns of Colon and Panama, at the northern and southern end of the Canal, are not under the jurisdiction of the commission as far as regards liquor-selling. There is no restriction on an employee going to these towns and getting liquor as he wishes and bringing it out into the Zone to his own home. The only prohibition is that it must not be sold in the Zone. But to get liquor he has to make a longer or shorter railroad trip, and go to considerable effort. Our experience has shown that there are a considerable number of men who do not care enough for liquor to make the effort, and therefore do without. Of course there are a large number who bring liquor out and drink as much as ever; but on the whole our prohibition of its sale has largely decreased drunkenness. It has increased the efficiency of our working force so much that generally the men in charge of the laborers in the different districts have asked to have their districts included within the prohibited area. I believe that it would be best for the native on the Rand to have no alcohol at all.

That alcohol is not a necessity for the native is evidenced by the condition of affairs at the De Beers mine. There they have compounds that are kept rigidly closed. Neither kaffir beer nor any other alcohol is given him. Yet he remains in perfectly good health and seems contented. He likes the life at Kimberly better than he does that on the Rand. This is evidenced by the fact that their force is always full, yet they do not have to recruit, whereas on the Rand the opposite is the case.

One cannot see these mines, or look over their statistics, without being struck by the many advantages a closed compound has in the management of these semicivilized natives.

MEDICAL SERVICE

Attention should be given to the methods at present in vogue of getting the East Coast boy from his home to the mines. In my opinion there is opportunity here of the native becoming infected with both pneumonia and tuberculosis before he reaches the mines.

In any case some machinery is needed for carrying out a system of sanitation. You have on the Rand now about fifty-four mines, each entirely independent as to the sanitation and care of the sick. About thirty-eight physicians are employed by these mines. Each is doing the same work as the other. That is, each man on his own mine has to do the surgery, the medicine, the pathologic work, the sanitary work and the Roentgen-ray work. It is impossible for each man to be specially qualified in all these branches. You have sixty-two hospitals, treating 2,150 patients. None of these hospitals is equipped or manned in a first-class manner. In general, the larger the hospital the better manned and equipped. The nursing force in native hospitals is made up of natives who have neither the intelligence nor training for such work. All is being done, probably, that can be done under the present system of numerous small hospitals. It is impracticable from an economic point of view to equip all these small hospitals with a first-class instrument outfit in every direction, and if it were possible economically, one doctor could not acquire the skill and experience for using them all. If a combination could be effected, a much higher state of efficiency could be brought about at no increase of cost. If all the sick could be brought together into one hospital, they could be cared for at less cost than in sixty-two hospitals. You could select the best qualified doctor among your present men, and put him in charge of the surgery. With such a service as he would have, in the course of a few years, he would become the peer of any surgeon anywhere, and you would be able to give your employees as good surgical attention as the very wealthiest could command. You could afford to equip such a hospital with first-class surgical appliances of every kind at a less cost than the moderate supply at present given to the sixty-two hospitals now in use. The same could be done on the medical side.

In the Bacteriological Institute you already have an institution and personnel that could be used for the pathologic work, and the patient could be brought to hospital by the railroad, which connects with all the mines, and by motor ambulance and wagons.

With 200 white trained nurses, male and female, in such an institution, you could select your subordinate native nurses from the more intelligent and better educated natives, and thus secure a first-rate nursing force.

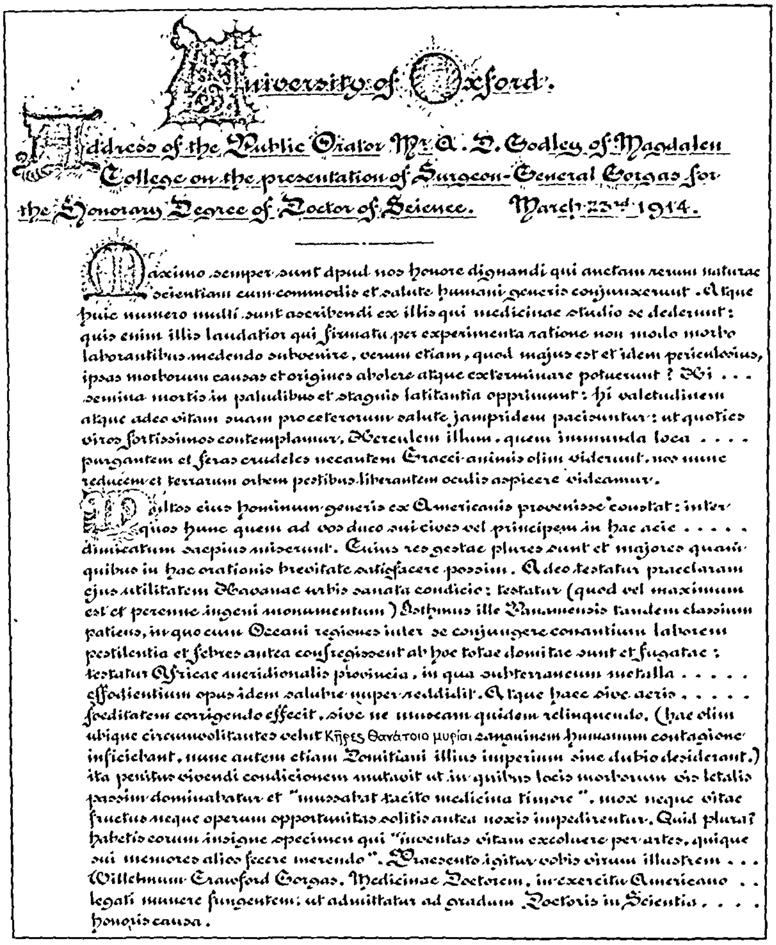
Such a hospital scheme has been adopted by us on the Isthmus for our force of 60,000 men scattered along a railroad 50 miles in extent, and it has been for us both economical and satisfactory. I believe that you could adopt the same plan for your 200,000 men, who, it seems to me, are in a comparable condition.

The construction of such a hospital need be no more expensive than your barrack construction, if the hospital were built in single story on the pavilion plan. I believe that eventually you will have to provide more barrack space, and the present hospitals could be used as such.

In a large hospital of this kind you could keep in better touch with the character of disease affecting the employees, which is in itself a considerable sanitary advantage.

With a pathologic department making all the necropsies, you would have greater protection than you now have on the question of paying claims, and greater accuracy and uniformity in diagnosis.

You could select the men best fitted and place them in charge of the sanitary work. These men should devote their whole time to their work, and be in thorough and constant touch with the sanitary conditions of all the mines. One man should be chief, and on the staff of the Chamber of Mines; he should be responsible to the Chamber of Mines, and entirely independent of the management of the individual mines. There need be no conflict with the present public officials in such an organization. If such an organization were in effect now, when the chief sanitary officer of the Chamber of Mines found a mine not complying with the present public sanitary ordinance, he would report the matter to the Chamber of Mines. The Chamber of Mines could either take the matter up with the mines concerned, or directly report the defect to the medical officer of health of the district. If it were the enforcing a sanitary measure not covered by public ordinances, but which had been authorized by the Chamber of Mines, the chairman of the chamber could take the matter up directly with the mine management. For instance, if the mines at present associated had authorized the Chamber of Mines to enforce as far as possible dispersion, the measure which I recommend for the sanitation of pneumonia, the chief sanitary officer would be in constant touch with all the compounds. He would have in view the desirability of increasing the married location as rapidly as possible, so far as was compatible with economy and expediency. If, under these circumstances, the chief sanitary officer found a mine where the married location was full, and there were applicants on hand for additional married quarters, he would urge the erection of additional accommodation on the mine management. If a satisfactory agreement could not be arrived at between them, the chief sanitary officer would take the matter up with the Chamber of Mines.



University of Oxford.

Address of the Public Orator Mr. A. D. Godley of Magdalen College on the presentation of Surgeon-General Gorgas for the Honorary Degree of Doctor of Science. March 23rd 1914.

Maximo semper sunt apud nos honore dignandi qui auctam rerum naturae scientiam cum commodis et salute humani generis conjunxerunt. Atque huic numero multi sunt ascribendi ex illis qui medicinae studio se dederunt: quis enim illis laudatior qui firmata per experimenta ratione non modo morbo laborantibus medendo subvenire, verum etiam, quod majus est et idem periculosius, ipsas morborum causas et origines abolere atque exterminare potuerunt? Hi . . . semina mortis in paludibus et stagnis latitantia opprimunt: hi valetudinem atque adeo vitam suam pro ceterorum salute jampridem paciscuntur: ut quoties viros fortissimos contemplamur, Herculem illum, quem immunda loca . . . . purgantem et feras crudeles necantem Graeci animis olim viderunt, nos nunc reducem et terrarum orbem pestibus liberantem oculis aspicere videamur.

Multos eius hominum generis ex Americanis provenisse constat: inter quos hunc quem ad vos duco sui cives vel principem in hac acie . . . . dimicantem saepius viserunt. Cuius res gestae plures sunt et majores quam quibus in hac orationis brevitate satisfacere possim. Adeo testatur praeclaram ejus utilitatem Havanae urbis sanata condicio: testatur (quod vel maximum est et perenne ingeni monumentum) Isthmus ille Panamensis tandem classium patiens, in quo cum Oceani regiones inter se conjungere conantium laborem pestilentia et febres antea confregissent ab hoc totae domitae sunt et fugatae: testatur Africae meridionalis provincia, in qua subterraneum metalla . . . . effodientium opus idem salubre nuper reddidit. Atque haec sive aeris . . . . foeditatem corrigendo effecit, sive ne muscam quidem relinquendo. (hae olim ubique circumvolitantes velut Κῆρες θανάτοιο μυρίαι sanguinem humanum contagione inficiebant, nunc autem etiam Domitiani illius imperium sine dubio desiderant.) ita penitus vivendi condicionem mutavit ut in quibus locis morborum vis letalis passim dominabatur et "mussabat tacito medicina timore", mox neque vitae fructus neque operum opportunitas solitis antea noxis impedirentur. Quid plura? habetis eorum insigne specimen qui "inventas vitam excoluere per artes, quique sui memores alios fecere merendo". Praesento igitur vobis virum illustrem . . . Willelmum Crawford Gorgas, Medicinae Doctorem, in exercitu Americano . . legati munere fungentem: ut admittatur ad gradum Doctoris in Scientia . . . . honoris causa.

Fig. 1.—Address of the Public Orator of the University of Oxford on the presentation of Surgeon General Gorgas for the honorary degree of Doctor of Science. Made on sheepskin in four colors (see editorial department). In the original the following English translation is appended. That it may be more easily read we have reproduced it letter for letter.

THOSE are most to be honoured by us who have increased knowledge and thereby promoted the welfare of the world. Such are many students of medicine: it is a fine thing to have the scientific knowledge which can cure disease: but theirs is a still finer if more dangerous task who can extirpate the causes from which disease springs. It is such men who destroy the seeds of death which are bred in swamps, risking their health and even their lives to serve their fellows. These heroes are a modern realization of the legend of Heraclu, the cleanser of foul places and the enemy of evil beasts.

THE eminent American who you see today has like many of his countrymen fought in the forefront of the battle. His achievements are too numerous for me to relate in detail. Suffice it is say that it is he who cleansed Havana: it is he who put fever and pestilence to flight in the Isthmus of Panama, and made possible the long-thwarted construction of the great inter-oceanic waterway: it is he who has recently improved the sanitary conditions of the South African mines. He purified foul air; he waged war on the myriad swarms of death disseminating mosquitos. The result has been an amelioration of the conditions of human life in plague-haunted districts, where once "in silent fear the helpless healer stood", and it is now possible to live in comfort and to work with advantage. There can be no better example of those "Whose skill hath served the human lot to raise, and won a name that endless ages praise."

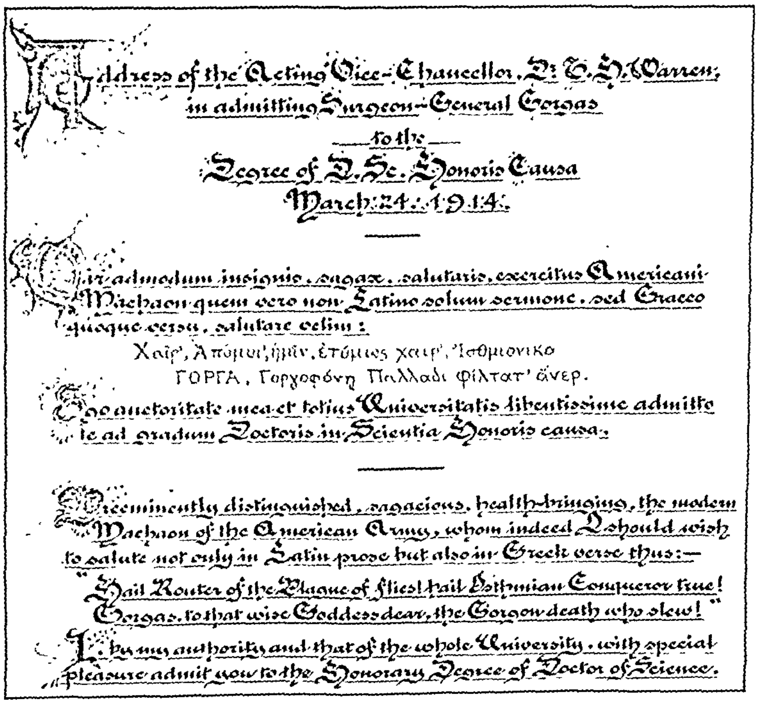
Or, if the chief sanitary officer found the pneumonia rate high in any particular compound or building, he would see that the proper corrective measures, as outlined above, were applied. On the other hand, in compounds and buildings in which the health-rates were satisfactory, he would not make any change. Such effort applied for a year or two would gradually bring about a uniform system of sanitation. If you had had such a system for the past few years, a sufficient force constantly devoting their whole time and attention to sanitation, you would have by this time reduced pneumonia to a minimum. If it were adopted now, I believe that at the end of a few years pneumonia would be reduced to a minimum. If it were feasible to adopt the whole scheme as outlined, which is the scheme that we used at Panama, I see no reason why the results should not be the same, the rapid reduction of pneumonia to a minimum. Your native labor force is evidently undergoing a gradual process of immunization. In 1903 and 1904, your total rate from pneumonia was 25.31 per thousand.[1] For the first nine months of 1913 this had fallen to 8.8 per thousand per annum. The fall has been more rapid during the last months of this period, on account of the stoppage of the introduction of the more susceptible native from the tropical regions north of latitude 22. This process will continue going on for several years till the whole of the native laboring population reaches the state of immunity that the Cape native has now. This, I take it, is the maximum that the native is capable of reaching under your present sanitary conditions. I think that this could be still further reduced by the sanitary improvements suggested. I base this opinion on our experience on the Isthmus, where the negro pneumonia rate has been reduced from 18.74 in 1906 to 0.42 for the first eight months of 1913. During one month in 1906, it was higher than it has ever been on the Rand for a similar body of men, and for a similar period, 43.41 per thousand. Meanwhile, if you introduce the native from the non-immune regions, your rate will go up. This, I think, could in great part be prevented by housing the tropical native in huts as suggested, and by furnishing him with cooked or uncooked food to be purchased as he liked. In the course of a year or two he would acquire immunity, and would then be on the same footing as a boy from the South. The success of any system of sanitation which is more or less new to any locality will depend a great deal on the choice of the man who has the charge of carrying it into execution. If he believes in it, has tact, and is enthusiastic and persevering, it will succeed. If he is discouraged by difficulties and opposition, he will fail even if his system is correct. He will find many men who have ideas of their own on these subjects, and who will point out the impossibility of carrying out the plans agreed on. It will be the health officer's business to familiarize himself with all the details involved and to find reasonable means for meeting reasonable objections.

Of these sanitary recommendations, I consider that of increasing the floor space to about 50 feet the most important and pressing, and by far the best way of doing this to be the village hut system and the introduction of families. If this particular method cannot be carried out, effort should be made to come as near it as feasible.

Second in importance, I consider improvement in the hospital system and care of the native sick. This can be best carried out by a central hospital. If a central hospital is not feasible, such concentration of hospitals as is possible should be made.

The third in importance is the establishment of a central sanitary bureau or department under the Chamber of Mines, the head of this department to represent the mines on all sanitary questions.

The present regulations regarding matters of sanitation should be revised so that the sanitation of the mines might be accomplished by the authority of one official, government or municipal, instead of with five different interested parties, as is now the case.



Address of the Acting Vice-Chancellor, Dr. T. H. Warren,
in admitting Surgeon-General Gorgas
to the
Degree of D. Sc. Honoris Causa
March 24. 1914.

Vir admodum insignis, sagax, salutaris, exercitus Americani Machaon quem vero non Latino solum sermone, sed Graeco quoque versu, salutare velim:

Χαῖρ', Ἀπόμυι', ἡμῖν, ἐτύμως χαῖρ', Ἰσθμιονίκα
ΓΟΡΓΑ, Γοργοφόνῃ Παλλάδι φίλτατ' ἄνερ.

Ego auctoritate mea et totius Universitatis libentissime admitto te ad gradum Doctoris in Scientia Honoris causa.

Preeminently distinguished, sagacious, health-bringing, the modern Machaon of the American Army, whom indeed I should wish to salute not only in Latin prose but also in Greek verse thus:—

"Hail Router of the Plague of Flies! hail Isthmian Conqueror true!
Gorgas, to that wise Goddess dear, the Gorgon death who slew!"

I, by my authority and that of the whole University, with special pleasure admit you to the Honorary Degree of Doctor of Science.

Fig. 2.—Address of the Acting Vice Chancellor in admitting Surgeon General Gorgas *to the degree of* Doctor of Science. Reproduction of an illuminated manuscript made upon sheepskin in four colors: red, gold, blue and black.

Report of Tuberculosis Commission in Kentucky.—Kentucky, by an act of the legislature, established a commission in 1912 for the study of tuberculosis. The first report of that commission, a cloth-bound pamphlet of sixty pages, sets forth what has been accomplished. The work so far has been chiefly preliminary and educational. An exhibition car and moving-picture exhibit, teachers' institutes, a nursing service and the distribution of much printed matter have been some of the means employed. Special county campaigns in cooperation with local organizations have also been conducted. The further work of the commission will consist not only in keeping up the educational campaign, but also in the establishment of local sanatoriums in the districts into which the state is to be divided. The report shows that much interest has been aroused and much good work done.

---

[1] Final Report of Mining Regulation Commission, i, Table 1.

THE TREATMENT OF HEMORRHAGIC DISEASE OF THE NEW-BORN BY DIRECT TRANSFUSION OF BLOOD

WITH A CLINICAL REPORT OF FOURTEEN PERSONAL CASES

V. D. LESPINASSE, M.D.
CHICAGO

The chief causes of this condition are: syphilis, infection, hypoplasia of the coagulating elements of the blood and asphyxia. External factors, such as parity, the fetal presentation, duration of labor, complications of labor, obstetric operations and chloroform, are of minor importance. Syphilis, according to Holt, is a causative factor in from 2 to 6 per cent. of the cases, contrary to a generally current idea that syphilis is always the cause.

The pathology of this condition is yet rather obscure. In nine personal post mortems, Townsend states that there were no gross lesions except the hemorrhages, and in one case the blood-culture was negative. He also reports eighty-one post mortems from the literature, in most of which no lesions of any sort were found, except hemorrhages. In a few cases the following lesions were present: lesions of syphilis, enlarged spleen, enlarged liver, inflammation of the umbilical and portal veins and acute fatty degenerations.

Some cases give a positive and others a negative blood-culture. The bacteria found are the common ones. Wassermann reactions have been made in a few cases, and are positive in some and negative in others. The chief pathologic lesions are the same as the clinical lesions, namely, hemorrhage and its consequent anemia.
